GARDENER'S AND BOTA

DICTIONA

CONTAINING

THE BEST AND NEWEST METHODS OF CULTIVATIN

KITCHEN, FRUIT, AND FLOWER GA

OF PERFORMING THE

PRACTICAL PARTS OF AGRICU

OF MANAGING VINEYARDS,

AND

OF PROPAGATING ALL SORTS OF TIMBER TREES.

BY THE LATE

PHILIP MILLER, F.R.S.

GARDENER TO THE WORSHIPFUL COMPANY OF APOTHECARIES AT THEIR BOTANIC GARDEN IN
AND MEMBER OF THE BOTANIC ACADEMY AT FLORENCE.

TO WHICH ARE NOW FIRST ADDED,

A COMPLETE

ENUMERATION AND DESCRIPTION OF ALL PLANTS HITHERTO KNOW

WITH THEIR

GENERIC AND SPECIFIC CHARACTERS,

PLACES OF GROWTH, TIMES OF FLOWERING, AND USES BOTH MEDICINA
AND ECONOMICAL.

THE WHOLE CORRECTED AND NEWLY ARRANGED,

WITH THE ADDITION OF ALL THE MODERN IMPROVEMENTS IN LANDSCAPE GARDENING,
CULTURE OF TREES, PLANTS, AND FRUITS,

PARTICULARLY IN THE VARIOUS KINDS OF HOT HOUSES AND FORCING FRAMES.

WITH PLATES EXPLANATORY BOTH OF THEM, AND THE PRINCIPLES OF BOTANY.

BY

THOMAS MARTYN, B.D. F.R.S.

REGIUS PROFESSOR OF BOTANY IN THE UNIVERSITY OF CAMBRIDGE.

IN TWO VOLUMES.

GARDENER's AND BO

DICTIONARY

KADALI. See Musa.
KAKIMARA. See Ficus.
KAKOSPERMA. See Genista.
KÆMPFERIA. (So named by Linnæus from Engelbert Kæmpfer, a celebrated traveller; he published Amœnitates exoticæ, Lemgo and Travels into Japan, 1727.)
Gen. pl. 2. Ed. 1. 1. Schreb. 2. Juss. 6.
Class 1. 1. Monandria Monogynia.
Nat. order of Scitamineæ.—Linn. Juss.

GENERIC CHARACTER.

Cal. Perianth superior, obscure.
Cor. one-petalled: Tube long: Border. Berries two-parted: the three alternate segments lanceolate, obtuse, small: the other two opposite, ovate, acute, concave, petal-like, the two from above less, all equal in length.
Stam. Filament five, awl-shaped, shorter than the corolla: Antheræ oblong, erect, double, converging, furrowed, emerging from the tube of the corolla.
Pist. Germ roundish, under the length of the tube: Stigma two-plated, roundish.
Per. Capsule roundish, three-lobed, three-celled, three-valved.
Seeds several.

Obs. It rarely bears fruit. The germ is found near the root.

ESSENTIAL CHARACTER.

Cor. Ex-parted, three of the parts larger, spreading, one two-parted. Stigma two-plated.

[This is an annual, fleshy plant, with a palmate, creeping, white root, and tall shaped stalk. Simple leaves. Leaves growing from the ground, oval, obtuse, with many longitudinal grooves. Flowers membranaceous, gibbous, spreading, having the tube white. Flowers radical, oblong, erect, with a large white spathe. Corolla blue, lower petal purple, petals many, awl-shaped, the two upper purplish. Corolla silver-coloured, long, slender, curved; border spread out, four-parted, three segments lanceolate-linear, curved towards a side, equal, longer, two alternate, ovate, the lowest broader, very blunt, shorter, purplish. Stamens fifteen, with a white

fort has roots somewhat like those
growing in large clusters, co-
coloured skin, but within white;
leaves, which fold over each
of an eight inches long,

4. Kalmia hirsuta. Hairy Kalmia.
Curt. magaz. 178.
Leaves ovate, alternated to both ends, peduncles axillary two-flowered.]

DESCRIPTION, &c.

1. Broad-leaved Kalmia rises with a branching stalk to the height of ten to twelve feet, with very little, which are two inches long and one broad, of a dark green on the upper side, and of a pale green on the under; they have short foot-stalks, and stand alternate; they have short foot-stalks, and stand alternate; they have short foot-stalks, and stand alternate

Rumphius observes that the leaves when bruised have a smell like violets; effects of the same kind.

Native of Java, Amboina, and the Philippines; where it flowers frequently in the year, and has commonly fruit and a ripe nut, shaped like the nutmeg of colour.

KLEISIA. See *Dillenia* and *Papaya*.

KNAWEL. See *Corrigiola*.

KNAUTIA. (*Dedicated by Linnæus, from Christopher Knaut, physician at Halle in Saxony, author of a Flora Halensis.*)

Gen. pl. 6. *Reich.* 1212. *Juss. Genera Plant.* 195.

Class and order. *Tetrandria Monogynia.*

Nat. order of the *Aggregate—Dipsaceæ.* Juss.

Gen. char. Common calyx contains two florules; proper calyx of each florule double; outer calyx, upright, quinquedentate; inner calyx, quinquefid. Corolla of the florule of the disk one-petalled, funnel-shaped, tube very small, scarcely the length of the calyx, quinquefid, regular; of the florule of the radius one-petalled, funnel-shaped, tube very small, scarcely the length of the calyx, quinquefid, irregular. Stamens four, inserted into the tube of the corolla, filiform, very short. Anthers oblong, incumbent. Pistil: germen inferior, ovate. Style filiform, length of the stamens. Stigma bifid, obtuse. Pericarp none. Seed solitary, invested, crowned with the calyx, and covered with the proper involucre of the florule. Receptacle common, chaffy, bristly.

Ess. char. Common calyx contains two florules; proper calyx of each florule double; outer calyx, upright, quinquedentate; inner calyx, quinquefid. Corolla of the florule of the disk one-petalled, funnel-shaped, tube very small, scarcely the length of the calyx, quinquefid, regular; of the florule of the radius one-petalled, funnel-shaped, tube very small, scarcely the length of the calyx, quinquefid, irregular. Stamens four, inserted into the tube of the corolla, filiform, very short. Anthers oblong, incumbent. Pistil: germen inferior, ovate. Style filiform, length of the stamens. Stigma bifid, obtuse. Seed solitary, invested, crowned with the calyx, and covered with the proper involucre of the florule. Receptacle common, chaffy, bristly.

Obs. The genus is differenced from *Scabiosa* by the indented calyx, and the bifid stigma of the flower.

SPECIFICAL CHARACTERS.

Cal. common oblong, simple, quinquedentate. Florules proper double, superior, *Corollæ* irregular. *Receptacle* chaffy.

1. Rose pendulous, & hyp. [illegible] upright, retrorse usually more or less rose in bright sun [illegible] & free light, cylindrical, attenuated by its upper narrow end [illegible] Lower leaves [illegible] upper ones [illegible] [illegible] [illegible]

feed on its green leaves with impunity, yet when cattle and sheep, by accidentally devoured of better food, eat the leaves, many die suddenly. I shall not, may, and continues to flower a great part of the summer.

The wood, being very hard, is very useful in smaller works. The Indians are said to make small dishes, spoons and other domestic utensils out of the excrescences, or knots, of a tree, excavated and gently wrought over a gentle heat, which become hard and smooth. After several unsuccessful attempts to propagate it in England, Mr. Catesby procured plants of it in Jamaica, which arrived safe, and with little further success, till the year 1726, Captain Cornwall, then Governor of Providence, sent a number of plants to Mr. Collinson, which have since flowered in England, some smaller, and others with larger flowers, in July 1740, in Mr. Collinson's garden at Mill-hill.

According to the Rev. Dr. Dickson, it was introduced by Mr. Peter Collinson in 1736.

A specimen raised from seeds, sown in the open ground, flowered in the garden of Mr. Robert Barclay, at Bury Hill, Surrey, in July 1796. The flowers are produced in large terminal corymbs, and are of a pale purple colour. The leaves are opposite, ovate, entire, and smooth on both surfaces, on footstalks. Flowers in lateral or axillary corymbs, not accompanied, as those of the preceding are, by small and deeper coloured.

The varieties with pale and deep red flowers differ in their native state, the small humble of the two, not only produce the small brilliant flowers, but in greater abundance.

This also is reputed poisonous to sheep and cattle in North America, of which it is a native. Introduced in 1736, by Mr. Collinson?. Catesby says, it flowered at Peel, June 1743.

2. Glaucum Kalmia is much inferior in size to *latifolia*, rarely exceeding two feet in height. It is a native of Newfoundland, where it was discovered by Sir Joseph Banks. Cultivated in the Botanic Garden, Chelsea, in 1767. Flowers in June and July.

3. Hirta, Kalmia with the general appearance of *latifolia*, but differs in having the leaves, stalks, and flower-stalks hairy. The flowers are about the same size with those of the preceding, but of a deeper colour, and grow in corymbs. Native of Carolina. The sole specimen known, the stalk, leaves and calyx closely covered with hairy bristles. It was presented from Carolina to the botanic garden, by Mr. Watson, entirely void of blossom, and Kalmias several plants of it flowered about the middle of September.

KALMIA, *wood laurel.*

Wood flowers are the most charming ornaments in North America, and adorn upon the whole, if the plants are not removed. The seeds seldom germ in England, and those which are sent from America fail in the account a whole year before the plants appear, and are rarely more than a few plants. The late Mr. James Gordon was the first who succeeded in raising the plant from seeds. The plants that come from the seeds are more hardy to produce others, and come to flower much sooner.

The proper soil and culture of this shrub not being well understood in Mr. Miller's time, they were then but seldom in England.

They succeed best in a northern aspect, well sheltered, in a soil composed of loam and bog earth, in a

10. Red Canadian. 11. Roman. 12. Prince. 13. Royal. 14. Egyptian Cos.

(Garden) Lettuce is named in German *Gartensalat*. In Dutch *Tuinsla*. In French *La Laitue ordinaire*. In Italian *Lattuca*. In Spanish *Lechuga*. In Portuguese *Lactuca*.

3. Root biennial, very full of milky juice, as is every part of the plant. Stem upright, two cubits high, round, prickly, leafy, branched at the top into a single, close, prickly, leafy, terminating tuft of pale flowers. Leaves alternate, sessile, oval, prickly on the margin and the rib on the back, numerous, pale spines about an inch long, the uppermost deeply lobed and finned, those on the stem ranged perpendicularly, and not horizontally as in both others. Calyx smooth. Flowers small. Receptacle naked, pale, tow-coloured, smooth. Seeds ovate, somewhat flattened, oval, compressed, more or less brown, striated, crowned with a pale brown pappus, consisting of numerous, capillary, unequal bristles, and supported by a long, slender, pale, brown, striated footstalk.

The remotest leaves, gradually nearer and nearer to the stem, are more and more deeply lobed, and the lobes more and more pointed, till the uppermost are entire, lanceolate, and pointed. The flowers are small, and the plant is annual.

Native of the southern parts of Europe, with us in the Isle of Ely, on the borders of fields, as near Denny Abbey, &c.

4. Root biennial. Stem four or five feet high, prickly below. Root-leaves oblong, wedge-shaped, undivided, marked with prickles, embracing, obtuse, somewhat sinuated, finely toothed; floral-leaves sagittate, half embracing, most of the ear, terminating in a long point, and the base of each flowering branch. Flowers numerous, small, and pale yellow. Seeds flattened, and ribbed; very like those of L. sativa in all respects, except that the edges and keels near the top of the seed are rendered rough by very minute prickles.

According to Gerard and Hudson, this is a variety of the preceding, which though large, acrid and bitter in every organ, is scarcely much taller than, and not easily to be distinguished from L. virosa by its paler colour, its less spreading branches, and its narrower leaves.

Native of the meadows parts of Europe, by hedges, waste places, and borders of fields. In England, about Wrotham in Kent, Kingsland near the Bankside, Hackney between Bow and Walthamstow, Barnsbury and other places in Cambridgeshire, Old Ford, Bunhill, Tothill Fields, Marylebone, Oxfordshire, in a stone quarry at Tramp Arch in Yorkshire.

5. Scarious. Head as a variety of this.

Lettuce-vine, or the great Wall Lettuce, remains with a woody stock, of which the oldest parts are of very considerable strength, insomuch that the stem exhibited by Mr. Miller in the museum of the Chelsea Physic Garden was cut into planks, and used for the purpose of making a floor to a small room. When dried, the juice of this plant is said to be a powerful opiate, and is sometimes given in the form of extract in the quantity of a few grains, but it is not often employed for the purposes of medicine.

Dr. Cullen tried extensively the effects of this and of other species of lettuce, which were found by him to possess the virtues of opium, though in a much weaker degree. It is certainly a powerful narcotic, and may be used with advantage in many cases where opium is improper.

6. Leaves sinuate at the base, the lower pinnatifid, segments lanceolate, obtuse, sinuate, finely toothed, with a sharp point at the end. Stem upright, terminating one long, the upper ones many-flowered panicle. Flowers small, yellow. Seeds ovate, compressed, striated, crowned with a pale brown pappus, consisting of numerous, capillary, unequal bristles, and supported by a long, slender, pale, brown, striated footstalk.

Native of Canada. It was cultivated by Mr. Miller in 1759, and probably earlier at Chelsea Physic Garden. This bears a great resemblance to the preceding species with this in its lobby narrow leaves, but the leaves are [illegible] Indian Lettuce, the seeds are [illegible] more branched and [illegible].

Observed in the island of Java by Osbeck, [illegible] of other parts of the East Indies. [illegible] Sw. by Sir Joseph Banks, Bart.

7. Root perennial, composed of many [illegible] fibres, which abound with a milky juice, [illegible] partly to the ground. Stems several, [illegible] rising toward the top into several [illegible] leaves nine or ten inches long, nearly [illegible] pinnatifid to the middle, toothed on [illegible] the ends acuminate. Stem-leaves few, [illegible] Axe, clasp immediately below the [illegible] alternate entire. Flowers terminating [illegible] in pedunculus, [illegible] from two to [illegible] flower cathedra. Seeds [illegible] Clusius very [illegible].

Native of Germany, Italy, and France [illegible] 1683.

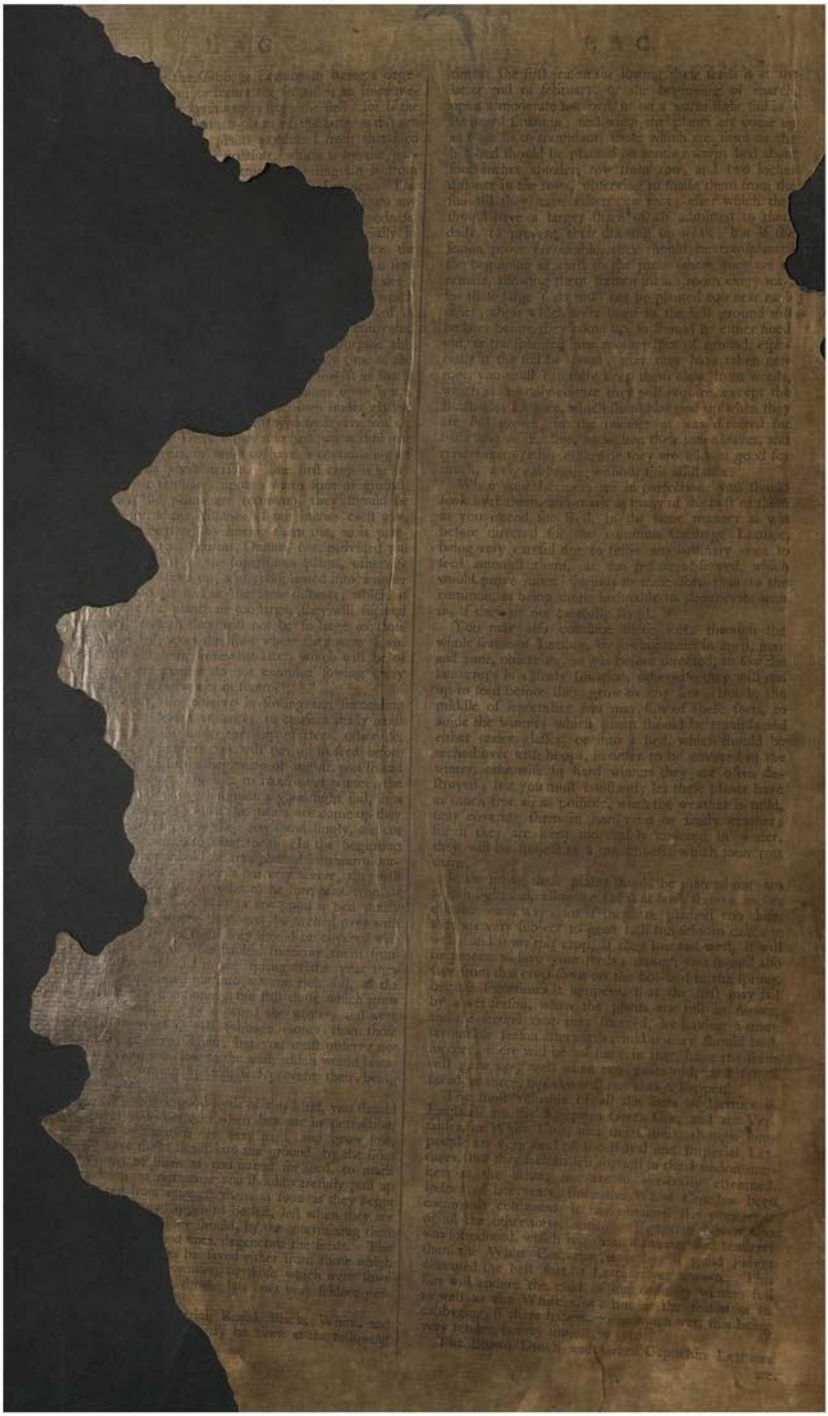
8. Root annual, fusiform. Stem [illegible] smooth, straight, very brittle [illegible] about the middle, branches [illegible] Leaves half-embracing, ear[illegible] very [illegible] base, the [illegible] with smaller [illegible] the lowest [illegible] deeply green colour, the upper ones [illegible] border, and some [illegible] toothed. Flowers [illegible] pedunculi and panicled. Petals [illegible] Seed dirty white. The whole plant [illegible] one valley, without any [illegible].

In sandy places by the sides of [illegible] the Great St. Bernard, and in the valley of Aosta [illegible] St. Pierre and Villeneuve.

Mont Villars has another species, which he [illegible] L'Chaix, because it was discovered by [illegible] According to him it is distinct from [illegible] Cichorium quadrangulare minus [illegible] some affinity to it. The leaves are [illegible] L. [illegible] sickings acuta, from [illegible] appear [illegible] but it is distinct from [illegible] at length.]

PROPAGATION AND [illegible]

The common Lettuce is [illegible] raising, to mix with other small [illegible]



as very hardy, and may be sown at the same season as was directed for the common Cabbage Lettuce, and are very proper to plant under a wall, or hedge, to stand the winter, where many times they will abide when most of the other lettuce are destroyed, and therefore they will prove very acceptable at this time when few other sorts are to be had; they will also endure the heat and drought in the most other sorts of Lettuce which renders them very proper for low sowing; for very often happens in very hot weather, that the other sorts of Lettuce will run up to seed in a few days after they are come up, whereas these will abide a month or more in good order, especially if care be taken to cut the forwardest only leaving those that are not half grown to be left.

If these plants of these two last sorts are planted under frames, so as to receive but little or no cherry, they will be fit for use in April, which will prove acceptable to those curious lovers of Lettuces, and bring a very good price, will render them tender to resist those frosts, the same care should be taken to preserve only such as are very large and well cabbaged, otherwise the pests will be in danger and be good for little.

The Red Capuchin, Roman, and Perpignan Lettuce are very proper sorts, and cabbage very much, so that a few of them may be preserved as may also some of the Aleppo, for the beauty of its spotted leaves; though very few people care for any of these last as table, when the other more valuable ones are to be obtained; but as a rarity, these may supply the place pretty well, and these sorts are very proper for sallad. The seeds of these must also be saved from such as cabbage well, otherwise they will degenerate, and be good for little.

In saving seeds of all these sorts of Lettuce, you should observe never to let the plants stand near each other, for by their large spreading they will both vary from their proper kind and partake of each other's and there should be a space allowed by the like of each, to which the plants should be allowed, to prevent their being broken, or blown out of the ground by wind, to which the Cabbage, Cos, and the other large growing Lettuces are very subject when they are in flower. You must also observe to cut such branches of the large growing Lettuce as open first, and not wait to have the seed of one whole plant ripe together, which never happens; but, on the contrary, some branches will be ripe a fortnight or three weeks before others, and when you cut them, they must be spread upon a paper, cloth, or any place, that the seeds may dry, after which you should beat them out, and dry them again, and clean them for use, being careful to keep them from mice and other vermin, who love these seeds as well as they do, they will soon devour them.

(The wild sorts are usually raised from seed. Propagated [illegible] parted at the roots, and may be increased by cuttings.)

DESCRIPTION, *&c.*

This is an annual plant, about a foot high. The leaves resemble those of Honeywort (Cerinthe). The flowers are collected into spherical heads at the extremity of the stalks, and are of a greenish yellow colour.
[The fruit is small, pedicelled, ovate-acuminate, crowned with a ciliate calyx, villose, one seed only ripening, the other abortive and fixed laterally to the apex of the other, like a withered scalelet. The fertile seed is of a dusky black colour, sprinkled all over with hoary villose hairs, convex on one side, with five capillary raised whitish streaks, flattish on the other, with three very slender streaks, marking out the place of the abortive seed; which is constantly and easily found, when the fruit is well softened in water*.
Native of the Levant. Cultivated in 1708, by the Dutchess of Beaufort. It flowers in june and july*.]

PROPAGATION AND CULTURE.

Sow the seeds in autumn on a warm border, soon after they are ripe; or if they be permitted to scatter they will come up of themselves. When the seeds are sown in the spring, they commonly remain in the ground a year, and sometimes two or three years before they grow.

* Gærtner. * Hort. kew. * Cavanilles.

According to Monf. L'Heritier, it has the habit of Napæa, and the root is annual. He joins it with Hibiſcus, becauſe it agrees in all points with that genus, eſpecially in the pericarp, and the ſimplicity of the calyx, not of itſelf ſufficient to make it of a diſtinct genus. See his deſcription, &c. under Hibiſcus Solandra.

Murray contrary makes it a *Solandra*, and has deſcribed it under the name of *Trigueria*, from Heros a Spaniſh botaniſt.

Found in the Iſle of Bourbon by Commerſon, introduced into the Paris garden about the year 1778, and into Kew garden in 1786 by Mr. Zier[t].

Linnæus Solandra, which is the ſame plant.

Root round, not very fibrous. Stems branched [illegible], herbaceous, a foot high, villoſe, as is the whole plant. Leaves diſtant, alternate, on filiform petioles, ſhorter than the leaf: lower ternate, with ovate-lanceolate unequal leaflets, the middle one very long: upper cordate, ſubhaſtate-lanceolate, longer, quite entire. Stipules ſhort, deciduous. Flowers lateral, ſolitary, pedunculed; peduncles longer than the petiole, ſlender, bright, jointed near the flower, thickened. Calyx deeply cut into five lanceolate very acute ſegments, [illegible] permanent. Capſule within the calyx, ovate-acuminate, with three ſeeds in each of the five cells. Seeds black, kidney-form, rugged, with very ſmall tubercles. Native of Senegal, where it was found by Adanſon[t].

PROPAGATION AND CULTURE.

The ſame with thoſe ſpecies of Hibiſcus which require hot houſe from hot countries. The ſecond ſort ripens the ſeeds in England, and may be increaſed by them.

LAGURUS. (*From λαγως, a hare, and ουρα, a tail.*)

Lin. gen. n. 92. *Reich. n.* 98. *Schreb. n.* 123. *Gaertn. t.* 1. *Juſſ.* 30.

Spicatum tomentoſum longiſſimis ariſtis donatum. *Scheuch. gram.* 52.

DESCRIPTION, *&c.*

This is an annual graſs, growing to the height of a foot or eighteen inches, and even more, very ſoft and downy, as are alſo the leaves and ſpikes. Theſe are about two inches long and almoſt round, beſet with down of a pale ſtraw colour.—The corolla when ripe is ſhorter than the calyx, and proceeds the awns. Seed ovate, acuminate at both ends, on one ſide convex, ſmooth, on the other concave, with a longitudinal middle, bay-coloured[*].

A native of the ſouth of Europe, France, Italy, Sicily, Spain. Obſerved it in Narbonne, Italy about Naples, ſandy grounds, lower and ſmaller than is deſcribed above.—It was cultivated here in 1640, according to Parkinſon[†].

Leaves cordate blunt ſmooth, floral leaves ſeſſile, calyx deeply goſhed.

DESCRIPTION, *&c.*

1. [Root perennial. Stem from half a yard to almoſt a yard in height, hiſpid, branched, hollow, upright, frequently tinged with red towards the bottom. Leaves petioled, acuminate, veined, often red underneath, ſmooth and ſhining above. Whorls diſtant, from ſix to twelve or fourteen-flowered. Calyx ſeſſile, much wider than the tube of the corolla, ſmooth except at the edge and along the nerves, where it is villoſe. Corolla an inch long, of a deep red colour: tube ſtraight, cylindric, pale: upper lip obſcurely ſerrate or entire, ciliate: throat wide, marked with purple lines: lower lip trifid or rather biſid, emarginate, ſpotted, ſerrulate; the lateral ſegments bent down and dotted. The ſmell of the plant is very ſtrong and unpleaſant[a]: but the ſize and brilliant colour of the flowers have ſecured it a place in the garden, which no other ſpecies of this genus has a claim to.
Native of Italy, Sileſia, Hungary.—Cultivated in 1629[b], according to Parkinſon, who names it Hungary Dead-Nettle, or Dragon Flower.
β. Orvala garganica is a mere variety of this, owing its apparent difference to having grown in a moiſt ſhady place[c].
2. Root perennial, ſomewhat creeping. Stems purple, a foot high and more, almoſt upright, brittle, little if at all hirſute, branched. Root-leaves on very long petioles, floral leaves on very ſhort ones or none, petioles of the ſtem-leaves of a middling length, all ſerrate, ſcarcely pubeſcent, acuminate, not ſpotted. Whorls of flowers ſeparated by leaves, ten in a whorl at moſt. Calyxes ſmooth or very ſlightly pubeſcent, veined, the teeth ending in an awn or briſtle, the upper one more upright, the lower ones bent down, the middle ones ſtraight, all double the length of the belly. Corollas more than half an inch long, three lines wide, upright: upper lip blunt, ſlightly pubeſcent, bright purple and convex on the outſide; concave, white and ſmooth on the inſide: tube ſhort, curved inwards: throat wide, frequently ſprinkled with red dots: lower lip purple, round, ſpreading, ſerrate, ſmall, ſeldom bent back at the ſides[d]. Linnæus obſerves that the calyx reſembles that of the preceding.
Native of Italy, Sileſia, Siberia.—Introduced in 1775 by Drs. Pitcairn and Fothergill[e].
3. This plant is about a foot high. The flowers are larger than thoſe of the common ſort, and of a deep roſe-colour. Sometimes in cold ſituations it produces curled leaves, round like thoſe of the Lime-tree[f]. Native of Italy. Cultivated 1766, in the botanic garden at Oxford[g].]
4. Root perennial, creeping. Stems many, thick, a foot high. Leaves on long petioles. Flowers in whorls from the upper joints, large, of a pale purpliſh colour, continuing in ſucceſſion moſt part of the ſummer.
[Stems pubeſcent. Leaves bluntiſh, ſublobate and ſerrate, pubeſcent, but not rugged. Whorls many-flowered. Tube of the corolla ſtraight, [illegible] curved at the baſe as in the others. Upper lip [illegible]-toothed, ſpreading, not compreſſed[h].

Loureiro

Loureiro describes the stem as perennial, upright, and three or four feet high; the leaves as unequally notched; the flowers as white-purple, in whorled spikes, with the upper lip entire, and the lower two-lobed.

Native of Italy, Silesia, China, Cochinchina and Japan.—Cultivated in 1729, by Mr. Miller[1].

5. This is very nearly allied to the next sort, or common White Archangel. It differs from it in having a purple corolla, the leaves marked with a longitudinal white area, which however disappears in summer; the petioles not widened; flowers five on each side, not ten; two teeth on each side of the throat, the upper one bristle-shaped[2].

Villars remarks, that the leaves vary much in their size and manner of notching, and that they are not always acuminate, but even blunt: the calyx also varies, being sometimes smooth, sometimes villose. He even doubts whether this, the Orvala and lævigatum be distinct species.

Native of Germany, Silesia, Dauphiné, Italy.

6. Root perennial, white, jointed, creeping. Stems numerous, a foot high, upright, unbranched, slender at bottom, hollow, slightly hairy, sometimes almost smooth; in exposed situations reddish purple; the young shoots weak and ascending. Leaves resembling those of the great stinging Nettle, unequally serrate; the tips of the little teeth red, and turned inwards, somewhat hirsute on both sides: the uppermost frequently coloured; those about the root often small, round and crenated. Petioles broader at the base, longer on the leaves next the root. Flowers in whorls, from ten to twenty together, yellowish white, sometimes tinged with red. Calyxes sessile, ribbed, hirsute, slightly decangular, with setaceous teeth, on the lower side at bottom marked with purple spots, and supported by a short linear bractea. Corolla twice as long as the calyx; tube nearly the length of the upper lip and crooked, anteriorly prominent below, and pressed in above; on each side the throat there are generally two little teeth; upper lip hairy, with a slight notch, and sometimes indented, distinguished by two elevated lines, which unite at the crown; lower lip bifid, turned back, slightly notched, and spotted at bottom. Filaments villose at top, a little thickened, and bent inward. Anthers dark blackish purple, with yellow pollen. Germ surrounded by a gland. Seeds three-cornered, with a little appendage at bottom[3].

It is common in hedges, on banks, and by road sides, and in corn fields; flowering in april and may, when it is much resorted to by bees, for the honey secreted into the bottom of the tube by the gland that surrounds the base of the germ[4]. Hence it is called in some counties *Bee-nettle*, which is corrupted into *Bean-nettle*. It has also the name of *Dea-nettle*, which is only a corruption of *Dead-nettle*, and that, as also *Blind-nettle*, means a Nettle without stings. In German it is *Taube Nessel:* in Dutch, *Dowe Netzl, Hondsnetel:* in Danish, *Doednelde, Dovenelde, Blindnelde:* in Swedish, *Blind nesla, Pigmesta:* in French, *Lamier, Lamion, Ortie blanche* or *morte, Archangelique:* in Italian, *Ortica morta* or *bianca:* in Spanish, *Ortiga muerta* or *blanca, Lamio blanco, Arcanjelica:* in Portuguese, *Ortiga morta* or *branca, Lamio branco.*

This plant has a disagreeable smell when bruised. Phalæna Chrysitis, or burnished-brass Moth feeds on it. Linnæus says, the leaves are eaten in Sweden as a pot-herb in the spring. No cattle, however, seem to touch it, and having a strong creeping perennial root, it should be extirpated, which is not difficult.

The flowers have been celebrated in uterine fluors, and also in disorders of the lungs. The bruised leaves have been recommended to discuss tumours. But it is discarded from modern practice.

7. Stems a foot or eighteen inches high, procumbent, tinged with red at bottom, and branched there; branches opposite, divaricating; middle stem higher than the rest, about one fourth of its height, has a pair of leaves with two barren calyxes; at the top three or four whorls. Leaves petioled, crenate, the notches after the fourth or fifth more deeply cut, lengthened out at the end, but blunt, slightly hirsute on the surface. Flowers in the upper whorls two together, almost an inch long, resembling those of the preceding in every thing except in the upper lip, which is divided into two revolute divaricate segments: the colour is white. The root-leaves are cordate, blunt and petioled. It flowers in february and march, is an annual plant, and a native of Italy near Naples, several places on the coast of Tuscany, and in the island of Elba. It may perhaps be a hybridous plant produced from the preceding and succeeding species[5].

8. Root annual, fibrous. Stems several, at bottom weak and branched, near the top almost naked, and frequently coloured, six inches or more in height, hollow, and somewhat rugged. Leaves veiny, slightly hairy or downy but not rough; the lower roundish-heart-shaped, notched, smaller, on longer petioles; the upper ovate-heart-shaped, bluntly serrate, on short petioles, growing close together, bent back and lying over each other, often of a reddish colour, especially at the ends. Petioles dilated at the base. Flowers growing thickly together on the tops of the stalks in whorls, six together in a double row. Calyx striated, hairy; teeth nearly equal, acuminate or awned. Corolla red, the lower border of the throat whitish with purple streaks; bright red in open situations, pale in the shade, and sometimes white: edge of the throat on each side furnished with two teeth, the uppermost pointed like a thorn, the lowermost blunter with a spot on it; the upper lip ovate, concave, slightly villose, entire; the under two-lobed, spreading a little and spotted. Seeds pale brown, triangular, truncate, margined.

This as well as the White Dead Nettle is common in most parts of Europe, in the same situations, and is a common weed in gardens and other cultivated land; flowering a great part of the year, from april to september, and in mild seasons both earlier and later. Bees resort also to this for the honey-juice in the flowers. According to Linnæus, it is boiled in Upland, a province of Sweden, as a pot-herb. The leaves and flowers have formerly been used in medicine, but are not regarded in the present practice[6].

The leaves vary much in form, size and toothing. Hence several varieties, one or two of which are considered by some as distinct species.

9. The leaves of this are deeply cut, so as almost to be lobed, and taper down into the foot-stalks[7]. Cultivated in a garden, it preserves its difference; and it is found with the preceding. It is annual, and not unfrequent, according to Ray in kitchen gardens and fallow fields[8]. Mr. Curtis observed it on a bank between Pimlico and Chelsea, and Mr. Robson about Darlington. Mont. Villars seems to regard it as intermediate between *purpureum* and *amplexicaule*. Mr. Miller's specimens are in the Banksian herbarium.

10. This is easily distinguished by the leaves being almost entire, neither serrate nor crenate. The flowers are white. Its native place is not known. It is perennial and flowers in april and may. Cultivated in 1683, by Mr. James Sutherland[9].

11. Root annual, fibrous, whitish. Stems several, nine inches or a foot high, nearly upright, smooth, with a few opposite branches. Lower leaves petioled, roundish heart-shaped, deeply crenate, veiny, slightly hairy; the petioles grooved on the upper part, and longer than the leaves; the upper ones semiorbicular, or in opposite pairs, broad heart-shaped, sessile, inclosing but not embracing the stem, with five scollopped lobes, the middle one at broad again, and with three leaflets at the end; the lateral ones small. Flowers in whorls, to fifteen, perfect and imperfect; the latter short, a little longer than the calyx, the tips very red, hairy and closed: the former four times the length of the calyx, bright purple, generally breaking out from the top of the stem. Calyx scarce manifestly striated; the teeth equal, acuminate, hirsute. The imperfect corollas are very hairy, of a bright red co-

[1] Hort. kew. [2] Linn. [3] Curtis. [4] Ibid.
[5] Cyrill. [6] Curtis. [7] Woodward. [8] Withering.
[9] Hort. kew.

lour, and have the mouth closed. The tube of the perfect ones is very long, cylindrical, and nearly upright: the edge of the throat is turned back, spotted, and has two little teeth; the neck is a little prominent; the upper lip hirsute and nearly entire; the lower turning down, and divided into two lobes, which are spotted with purple. Seeds covered with white spots and having a little appendage. These perfect flowers are like those of L. purpureum, but much longer.

The imperfect flowers appear in february and march; the perfect ones not till may or june: if the progress of the flowers be watched, it will be found that the corolla is gradually enlarged in different flowers, till the weather being sufficiently warm, they come forth fully formed. The imperfect flowers are neither rudiments of the long ones, nor are they barren, for they have both stamens and pistil. Linnæus informs us, that this plant scarcely ever produces perfect flowers in Sweden. Here then we have a process somewhat similar to what is observed in the Violet, and some other plants, in which perfect seed is produced, although the corolla be not perfectly formed; analogical to what happens in the animal kingdom, when a Caterpillar previous to its changing into the chrysalis state has been deprived of its proper quantity of food, the Fly comes forth perfect in all its parts except the wings, which are crumpled up and never extand.

This plant is common in most parts of Europe, in cultivated ground, on light soils, and on walls. The old name of it is *Great Henbit*.

12. Native of the Levant.]

13. Annual. Leaves marked with white, somewhat like those of the autumnal Cyclamen; they are smooth, and in dry weather have a musky scent, but in wet weather are fetid. Stems eight or nine inches high. Flowers white appearing in april. The seeds ripen in june.

[From Mr. Miller's specimens in the Banksian herbarium it seems to be a variety of Lamium album. The leaves are less acuminate, and the indentures are fewer and blunter.

PROPAGATION AND CULTURE.

Several of the species are considered as weeds rather than garden plants. The White Archangel propagates itself copiously by the roots, and the Purple by the seeds. Several which are here given as species, (2, 3, 5, 7, 9, 10, 13) are probably no more than varieties, and will increase of themselves in the same ways.]

1. Baum-leaved Archangel rarely produces good seeds in England, nor do the roots propagate very fast. The best time to part and remove these roots is october, but they must not be transplanted oftener than every third year, if they are required to flower strongly. It is hardy, and thrives best in a soft loamy soil.

[According to Mr. Curtis, it grows readily, but flowering about the end of april, it is then apt to be injured, if cold winds prevail, unless it be placed in a sheltered part of the garden.]

4. This may be propagated by seeds, but as the roots spread greatly, when it is once obtained it will spread fast enough.

Stem unarmed, leaves ovate ſerrate, flowers in axillary ſeſſile heads.

DESCRIPTIONS, *&c.*

[Theſe are moſtly ſhrubs, very few being herbaceous. The branches are quadrangular. The leaves oppoſite by pairs, except in a few caſes, where there are three or four together; ovate and wrinkled. Flowers aggregate in axillary and peduncled heads: each flower bracted.

1. This is about five feet in height. Trunk round or roundiſh, with an aſh-coloured bark. Branches at top, ſeveral, ſhort, aſh-coloured, and from theſe ſeveral others, a long ſpan or a foot in length, quadrangular, green, hairy. Leaves reſembling thoſe of Lamium album, above bright green and ſomewhat ſhining, beneath paler, deeply notched, much wrinkled, and very rugged. Whilſt the flower is yet cloſed, the lower part of the border appears of a pale red; when it opens, the tube and upper part of the border are ſaffron-coloured, but become reddiſh, and finally dark-red: this change of colour begins from the circumference and finiſhes in the centre. Hence the flowers in an umbel not being all opened at once, the middle appears of a ſaffron yellow, and the circumference of a red colour. From this change of colour and diverſity in the ſame umbel, this plant has obtained the name of *miſta* or *mixed*.

It differs from *L. aurea* in the leaves not being elliptic but acuminate, not ſlightly but deeply crenate, not even but much wrinkled, not dark green and ſhining very much, but pale green. The flowers alſo of that only change from a golden to a ſaffron colour; whereas theſe change from a ſaffron colour to a dark red [a].

Native of America. Cultivated in the Eltham garden before 1732.

2. Stem ſhrubby, branched, round, rugged: branches upright, round, rugged. Leaves petioled, three together ſeldom four, ovate-lanceolate, acuminate, nerved, the upper ſurface almoſt ſmooth, beneath ſomewhat hirſute, hoary. Spikes peduncled, ſubimbricate with lanceolate, entire, diſtinct and ſomewhat hirſute bractes; when young in a head, but afterwards an inch in length. Flowers pale blood-red and not changeable. Peduncles axillary, oppoſite, ſolitary, the length of the leaves, ſtriated, angular, hirſute. Calyx very minute, three-toothed, with the hinder tooth a little longer. Corolla ſalver-ſhaped, irregular: tube narrow, gibbous in the middle: border almoſt flat, oblique, four-cleft; upper ſegment almoſt upright, roundiſh; the lateral ones only half the ſize, ſpreading; the lower broader, waving; throat yellow. Anthers extremely minute, brownith green. Style the length of the tube. Fruit a berried drupe, red, roundiſh. Nucleus hard, two-celled [b].

Linnæus doubts whether this be ſpecifically diſtinct from *L. annua*, and Medicus does not ſettle the difficulty. It is clear however that this is a ſhrub.

Native of the Weſt Indies. Introduced before 1733, by William Houſtoun, M. D. (from the Havannah). His ſpecimen is in the Bankſian herbarium. It flowers from june to ſeptember [c].

Mr. Miller ſays, there is a variety with white flowers, and leaves not quite ſo round, entire on the edge.

[3. This is a ſhrub, with hairy, rugged branches. Leaves acute, ſerrate, wrinkled above, very rugged, ſoftly villoſe beneath, an inch and half long. Petiole dilated above. Peduncles oppoſite, the length of the leaves. Leaflets of the involucre lanceolate, a little ſhorter than the head. Corolla pubeſcent [d].

Native of Arabia, on mount Barah [e].

4. Stem hiſpid, quadrangular, ſtriated, ſomewhat woody. Leaves cordate, rugged, petioled, oppoſite but ſometimes three together. Spikes hemiſpherical, oppoſite, with lanceolate ſhorter bractes, and gradually lengthened out. Corollas fleſh-coloured, with a yellow throat, not changeable. Fruits purple.

Reichard is of opinion, that the plant deſcribed by Medicus (p. 222.) under the name of *Lantana trifolia*, is this ſpecies.]

It is an annual plant, riſing with a ſtrong, upright, rough ſtalk, near three feet high, dividing towards the

[a] Medicus and Dillenius. [b] Swartz. [c] Hort. kew. [d] Vahl. [e] Forſk.

top,

top, into two or three ereſt branches. Leaves ſerrate, by fours at each joint, a little woolly on their under ſide. Peduncles by pairs or three at a joint, from two to three inches long, ſuſtaining a thick ſpike of large purple flowers; which are ſucceeded by large, purple, ſucculent, eatable berries.

Sent by Dr. Houſtoun (before 1733) from La Vera Cruz, and received ſince from the north ſide of Jamaica. [Mr. Miller's ſpecimen is in the Bankſian herbarium.

5. Stem ſquare. Leaves very long and narrow, an inch and half in length, and one-third of an inch wide in the middle, toothed, of a dark colour above, whitiſh underneath, on their ſurface like thoſe of Sage, on very ſhort petioles. Peduncles axillary, two inches long.

Native of Jamaica, on mount Diablo [a]. Dr. Houſtoun ſent the ſeeds to Mr. Miller in 1730. The ſpecimen is in the Bankſian herbarium.

6. This is a ſhrub, native of the Weſt Indies [b]. It has its trivial name from the extreme ruggedneſs of the leaves.

7. Stem ſhrubby, a fathom in height, angular, ſomewhat rugged. Branches ſubdivided, almoſt upright, rugged, quadrangular. Branchlets quadrangular, grooved, ſtrict, hirſute, dark green. Leaves on long petioles, decuſſated, ſpreading, ovate, acuminate, ſerrate, nerved, hirſute. Flowers terminating. Peduncles ſhorter than the leaves, ſolitary, angular, grooved, hirſute. Bractes broad-lanceolate, concave, entire, pubeſcent. Calyx three-toothed, minute, the hinder tooth larger. Corolla funnel-form [c]: the tube and border at firſt pale ſulphur-coloured, changing to ſaffron, light red and pale crimſon [d]: tube round at the baſe, gibbous, widening towards the throat: border four-cleft, nearly equal; hinder ſegment almoſt upright, ſubcordate; lower broader, emarginate in the middle; the lateral ones entire, ſpreading, waved at the edge: throat contracted. Anthers minute, whitiſh. Germ oblong. Style ſhorter than the tube. Drupe the ſize of red Currants, black-green, with a nauſeous ſmell; nucleus two-celled [e].

Medicus doubted whether this were different from L. miſta or not, but after three years ſcrupulous obſervations he determined in the affirmative, from the difference in the leaves and colour of the flowers. The leaves in L. miſta are ovate-acuminate, deeply crenate, much wrinkled, rugged and pale green. In L. Camara they are more orbiculate, leſs crenate, ſofter, and dark green. The flowers of L. miſta become finally dark purple: thoſe of L. Camara are much paler, and change to tawny.

Native of the Weſt Indies. Cultivated in 1691, in the royal garden at Hampton Court. It flowers from april to ſeptember [f].

8. Leaves very much wrinkled, ſubtomentoſe. Bractes lanceolate [g].

Native of the Weſt Indies. Cultivated in 1758, by Mr. Miller. It flowers from may to november [h].

9. Native of Jamaica. Cultivated by Mr. Miller in 1758. It flowers from june to auguſt [i].

10. Stem round, woody, branched, ſcarcely hairy. Branches oppoſite. Leaves petioled, ſcarcely crenate, membranaceous, rigid, leſs wrinkled than in the others above, nerved beneath, tomentoſe. Leaves ſeldom if ever in threes. Peduncles ſhort. Spikes rounded. Bractes large, ſeſſile, cordate-ovate, with ſix or more nerves running in right lines from the centre, all a little excavated their whole length, and tomentoſe. Calyx very ſmall, whitiſh. Flowers of the ſame colour as in L. trifoliata, but the yellow colour of the throat ſoon changes to white; and hence the flower is whitiſh with a pale fleſh-coloured margin.

This ſpecies agrees in many reſpects with L. trifolia, as to the flowers: but in that the ſpikes are very long, the bractes ovate-lanceolate, the flower unchangeable; in this the ſpikes are ovate, the bractes cordate-ovate, the flowers changeable, with the throat whitiſh. In other reſpects they differ more eſſentially: for the ſtem of L. trifolia is ſquare; the leaves large, ovate-acuminate or lanceolate and ſerrate: whereas in L. involucrata the ſtem is round; and the leaves ſmall, orbiculate, and ſcarcely crenate [k].

Native of the Weſt Indies. Mr. Miller ſays, it was ſent him from La Vera Cruz by Dr. Houſtoun; but his ſpecimen in the Bankſian herbarium is marked Havana, 1731. It was cultivated here earlier, viz. in 1690, in the royal garden at Hampton Court. It flowers from may to july [l].

Scopoli thinks it not improbable that his *Zappania odoratiſſima* (Inſubr. 34. t. 15.) may be the ſame with this. But whether it be or not, he removes it from the genus Lantana, becauſe it is not didynamous, and has not either a four-toothed calyx, or a drupe for a fruit.

11. This is lower than moſt of the others, being ſeldom more than two feet in height. Stem round, aſh-coloured, not hairy. The younger branches have bundles of hairs ſpreading out at top. Leaves oppoſite, but ſometimes in threes, petioled, cordate-acuminate, more deeply crenate than in the other ſpecies; wrinkled, rugged and green on the upper ſurface; paler and tomentoſe-hairy underneath. Flowers axillary, with three peduncles, where there are three leaves. Bractes oblong, entire, tomentoſe-hairy, deciduous, differing in ſize. Colour of the corolla conſtant and always yellow [m].

Native of South America. Cultivated in 1732, by James Sherard, M. D. at Eltham [n].

12. Native of the Weſt Indies: where it was found by Mr. Gilbert Alexander. Introduced in 1774. It flowers in ſeptember [o].

13. Stem ten feet high, an inch and half thick, ſquare from top to bottom, armed with long, ſtrong, reflex prickles, or rather thorns, for they cannot be torn off without injuring the wood. Leaves ovate-oblong or cordate-oblong, wrinkled, rugged, crenate. Peduncles long, with fewer and ſhorter prickles. Colour of the tube of the corolla pale red: border lemon-coloured, changing into an orange and ſometimes deeper colour [p]. Drupe berried, ſoft, ovate, dark, very ſmooth, ſhining: fleſh pulpy, thin: ſtone bony, like a grape-ſeed, thick and blunt above, with two lateral lobules verging downwards, elongated below into a compreſſed conical beak; three-celled, the two upper cells fertile, the lower void. Seeds ſingle, obovate, remarkably acuminate downwards, compreſſed a little, white with a brown area at top [q].

Native of the Weſt Indies. Cultivated in 1692, in the royal garden at Hampton Court. It flowers from april to november [r].]

In our ſtoves it grows five or ſix feet high, and ſends out many branches. Leaves about an inch and half long, and three-quarters of an inch broad, hairy, on ſhort foot-ſtalks. Two peduncles ariſe from the axils, towards the ends of the branches, from each joint, one on each ſide; they are near two inches long, and are terminated by roundiſh heads of flowers; thoſe on the outſide are firſt of a bright red or ſcarlet, and change to a deep purple; thoſe in the centre are of a bright yellow, and change to an orange colour.

[14. Stem ſeven feet high, at firſt obſcurely quadrangular, but afterwards round, ſtriated, very thinly beſet with prickles, and not hairy. Leaves ovate-oblong or almoſt elliptic, bluntly notched about the edge, very ſhort ſtiff hairs at the upper ſurface, the lower rugged with a harſh down, dark green and ſhining as if they were varniſhed. Peduncles ſhort. Bractes deciduous, ſhort. Colour of the flower yellow, becoming golden and then ſaffron-coloured.

It differs from L. trifolia and involucrata in having oblong deciduous bractes, in the colour of the flowers, the form and ſplendour of the leaves; from L. meliſſæfolia in having the leaves ſhining and ſcarcely crenate, the flowers of a deeper dye and more changeable [s].

and theſe adhere ſo firmly to the receptacle, as not to fall off even in dried ſpecimens.

Gærtner remarks, that the ſeeds of the ray are almoſt ſtraight, wholly ſmooth, terminated by a ſpinule which is curved inwards; thoſe of the diſk ſickle-ſhaped, either pubeſcent with few villoſe hairs or ſmooth. He adds, that the ſeeds of Rhagadiolus cannot fairly be reckoned diſform, becauſe their diſformity is merely accidental, and proceeds from the calycine involucre.

Native of Iſtria, the Levant and Cochinchina. Cultivated in 1739 by Mr. Miller. It flowers in june and july.*] Mr. Miller affirms that he received the ſeeds from Portugal.

PROPAGATION AND CULTURE.

The firſt is a common weed. If the ſeeds of the other ſorts be permitted to ſcatter, the plants will come up better than if ſown in the ſpring. They require no culture.

Stem ſheathed, petioles dilated, leaves digitate linear elongated mucronate.

DESCRIPTIONS, &c.

1. Root the thickneſs of the finger or more, ſtriking two feet into the ground, pale brown on the outſide, white within, ſomewhat fleſhy, ſcarcely fibrous, perennial, having a very bitter ſubacrid unpleaſant taſte, and crowned with briſtles. Stem round, ſtriated, green with a glaucous bloom on it, ſmooth, filled with white pith. Sheaths of the leaves ſtriated, ſwelling. Rilis compreſſed with the forward edge ſharp. Leaves twice-pinnate: leaflets entire or with few lobes, toothferrate, obtuſe or acute, the lower petioled, the upper often ſeſſile, very ſmooth on both ſides or rough on the back only, firm, deep green on the upper ſurface, more glaucous and veined on the lower. Umbel upright, flat or ſomewhat convex, in the largeſt half a foot in diameter, compoſed of very many round ſtriated rays; leaflets of the involucre acuminate, ſpreading very much or reflex, pale green with ſometimes a purple edge, from five to ten in number. Partial umbel convex and cloſer, with a ſimilar involucre or none. Flowers white, petals inflex, obcordate, almoſt equal. Seeds ſmooth, flat on one ſide, having four, membranaceous, thin, ſubpellucid wings on the other, the outmoſt on each ſide broader; they have but little ſmell, and an unpleaſant ſubacrid taſte. It flowers in july, and the ſeeds are ripe in ſeptember.

It varies ſo much from ſituation that it might be miſtaken for different ſpecies, and ſeveral varieties are mentioned by authors. In the Alps it is only a foot or two in height, and ſometimes even ſhorter, with a ſtem entirely ſimple terminated by a ſingle umbel; it is alſo extremely ſmooth; more or leſs aſperity may however be obſerved on the leaflets and eſpecially on the ribs of ſome individuals; which is ſo remarkable in the large, lofty, branched plants of the lower regions. Theſe however become ſmooth when tranſplanted into a garden; and ſome leaves of the ſmooth alpine plants become hairy [a].

Native of many parts of Europe. Cultivated here in 1640, according to Parkinſon [b].

This acrid aromatic plant with ſomething of bitterneſs, ſeems to merit a place among the aromatic ſtimulants, emmenagogues, and aperient ſudorifics. It is uſed by the peaſants for themſelves, and by farriers for horſes in ſome countries; but not by regular practitioners. The root is the hotteſt part of the plant [c].

Mr. Miller has made ſeveral ſpecies out of this, but he has not deſcribed any.

2. The *L. trilobum* is diſtinguiſhed from *L. aquilegiefolium* by Murray and Jacquin. The leaflets of the former are cordate at the baſe, acute, and acutely ſerrate; whereas in the latter they are blunt. Haller's ſynonyms of n. 793. belong to this ſpecies; but he has deſcribed a variety of L. latifolium.

Jacquin thus deſcribes his plant. The whole of it is very ſmooth. Root perennial, round, a foot or more in length, with abundance of fibres at top, blackiſh on the outſide, white within with a yellowiſh pith in the middle, ſmelling when bruiſed, and having a bitter unpleaſant taſte. Stem round, from four to ſix feet in height, marked with lines but not grooved, firm, upright, ſhining, glaucous-green, becoming dark purple with age, having brachiate branches, and an aromatic ſweetiſh taſte. Sheath of the leaves long, concave, converging, ſtriated and embracing. Root and lower ſtem-leaves very large and tritternate, on long, ſubſtriated, ſolid, round or ſlightly compreſſed petioles. Upper ſtem-leaves ſeſſile and ſubternate; with the leaflets uſually three-lobed and gaſhed, ſharp with reddiſh teeth: ſometimes a ſingle three-lobed leaf is placed on the ſheath. Theſe leaflets however are all wide, and none of them linear. The middle ſtem-leaves are ſub-biternate, without any common petiole; and each either has its proper petiole, or the ſide ones alſo are ſeſſile. The pinnas both of theſe and the root-leaves are wide, blunt, lobed, gaſhed, glaucous and netted-veined on the back, ſmelling when rubbed. Univerſal involucre either wholly wanting, or conſiſting of one or two lanceolate, acuminate, concave, membranaceous leaflets, green edged with red. Partial alſo either none, or compoſed of few ſmall leaflets. Umbel wide, thin, flat, compoſed of ſtiff, ſtriated, round rays from two to three inches in length, and from ten to twenty in number. Partial more convex and denſe. Some of the central florets, having no piſtils, are abortive. Petals ſmall, white, attenuated at the baſe, inflex-cordate, equal and ſpreading very much. Anthers pale. Germ compreſſed, ſtriated. Styles awl-ſhaped, green. Fruit ovate-oblong, compreſſed, blunt. Seeds plano-convex with five ſhort pale membranaceous wings, and four others ſtill narrower between them.

Gærtner, who gives all the ſynonyms of Linneus, Jacquin, Haller, Morriſon and Rivinus, and unites the ſecond and third ſpecies of Murray, as we have done, ſeparates this plant from Laſerpitium, on account of the number of grooves, in the ſeeds, and there being no wings. He deſcribes the fruit as elliptic, turgidly lens-ſhaped, many-ſtreaked, conſiſting of two oblong-elliptic ſeeds, of a middling ſize; on the back are nine ſtreaks, alternately ſtanding more out, all rounded, without any veſtige of a wing; the belly flat or ſlightly concave.

Native of the Levant and Auſtria. Cultivated in 1640, according to Parkinſon. It flowers from may to july [d].

3. Root perennial. Stem not much branched, and having only one or two, ſeldom three leaves at the lower part: at the top are commonly two very large umbels. The wings of the ſeeds are very large, and frequently curled or waved. It varies with entire, rounded leaflets, agreeing in every other reſpect: and there are few plants that vary more [e].

Fruit ovate, ſomewhat gibbous, white or pale ſtraw-colour. Seeds plano-convex, with two dorſal and two marginal wings on the convex ſide, all membranaceous, fringed, and ſometimes entire, ſometimes gnawn at the edge: the flat ſide having a raiſed line along the middle [f].

Native of the South of Europe. Cultivated in 1683, by Mr. James Sutherland. It flowers in june and july [g].

4. Root perennial, white within and without but growing brown with age, ſeldom fuſiform and ſtriking downwards, but commonly tranſverſe and branched, unequal, a finger thick, fibrous, of a ſubacrid taſte and aromatic ſmell. Stem on open rocky hills perennial, one or two lines thick, and ſometimes not more than a ſpan high; in a lower ſituation among buſhes and on the borders of woods it grows to the height of four feet, with a ſtem the thickneſs of a pen. From one to three ſtems and more come out from the ſame root; they are upright, ſtriated, ſmooth, flexuoſe, branched. Membranaceous, ſtriated, channelled petioles inveſt the ſtem. Leaves manifold-pinnate, ſmooth: leaflets deeply gaſhed, flat; ſegments oblong, ſhortly mucronate. Pedunceles oppoſite to a leaf, upright, ſtriated. Umbels cloſe, flattiſh, compoſed of numerous rays. Umbellets ſimilar. Leaflets of the univerſal

[a] Jacquin. [b] Hort. kew. [c] Allion. and Krocker. [d] Hort. kew. [e] Villars [f] Gærtner. [g] Hort. kew.

universal involucre few, (sometimes only one) linear, seldom pinnatifid, half the length of the umbel: of the partial several, linear, the length of the umbellet. All the flowers fertile. Petals white or yellowish, almost equal, inflex-cordate, almost upright. Germ striated, oblong, smooth. Filaments many times longer than the petals. Anthers pale. Styles white, upright. Seeds elliptic, smooth, plano-convex, with five membranaceous wings.

Native of Carniola and Italy [a].

5. This is a lower plant than the first, not more than a foot and half or two feet in height; the leaves are much narrower; and the petioles are hairy. Flowers white. Seeds winged, curled [b].

Native of the southern parts of Europe. Cultivated in 1759 by Mr. Miller. It flowers in june and july [c].

6. Root perennial. Stem hirsute with white hairs, especially towards the base. Leaves having the appearance of *Cicuta virosa*, hirsute on the petioles and ribs: leaflets wedge-form-lanceolate, pinnatifid, not rigid. Umbels of the ray, involucres and flowers white. Seeds pubescent, acrid and aromatic [d].

Native of Prussia, Leipsic, Austria, Carniola, Dauphiné, Italy. Cultivated by Mr. Miller in 1759.

7. This is a biennial plant. The whole plant is smooth, has some smell when bruised, and a slightly aromatic acrid taste. Root subfusiform, the thickness of a finger, dirty white, with thickish fibres all round. Stem upright, firm, round, marked with lines, fistular, shining, branched from the axils of most of the upper leaves, green with dark purple spots. Branches under the umbel and the rays rough to the touch, when viewed with the microscope appearing muricated with white on the back of the streaks. Root and stem-leaves tripinnate; the upper ones pinnate. Rib grooved in front, angular in the other parts, not fistular, springing from a striated sheath. Leaflets pinnatifid, dark green on the upper surface: all the segments lanceolate, acute, most of them quite entire, unequal. Umbels erect, somewhat convex. Leaflets of the involucre about six, spreading a little, awl-shaped, acute, in a short time becoming brownish. Umbellets small, convex, distant, from twelve to twenty, with a similar involucre. All the florets fertile. Petals all equal, oval, with a narrow inflex tip, but not remarkably cordate, spreading very much and finally turned back, white but sometimes one or two half purple. Filaments purple at bottom, spreading very much, longer than the corolla. Style as the germ advances reflected. Germ yellowish at top, grooved along the border at each filament. Seeds subovate, smooth, brown, having an aromatic flavour without acrimony, but not pleasant, flat on one side, convex on the other, three-winged, and running out besides into a membranaceous wing at the edges [e].

8. From a thick oblong root, blackish on the outside, two or three leaves come out on long petioles, with a three-fold division, each again divided into three or five very narrow leaflets, almost two inches in length, and resembling grass leaves. Stem about a foot high, dividing into two or three branches, with a leaf at the base of each. Umbel of five, and sometimes of twelve rays, with an involucre both to that and the umbellet. Flowers white. Seeds striated and four-winged on one side, flat on the other.

Native of Monte Baldo [a].

9. Root perennial, with a thick head which is crowned with abundant brittly remains of former leaves, a foot and half in length, the thickness of the human thumb, round, with an irregular brown bark, fleshy and white within, with a yellowish pith. The whole plant smooth. Stem brachiate, round, marked with lines but not grooved, pale green or purplish, in subalpine meadows from one to two feet high, but in the lower mountains six feet in height. Leaves manifold-pinnate, smelling when bruised, aromatic, scarcely acrid, not pleasant. Ribs compressed, especially the lower ones, very finely marked with lines, shining. Sheaths wide, swelling, membranaceous, firm, marked with lines, pale green, embracing. Pinnules narrow-lanceolate, more or less acute, flat, glaucous green, subpetioled, most of them ternate, thickish. Universal involucre of ten or more, short, lanceolate or ovate, acute, concave, spreading or reflex leaflets. Partial similar but less. Universal umbel convex, from four to eight inches in diameter; rays roundish, smooth on the back, striated and roughish above, twenty or more. Petals white, almost equal, inflex-cordate, spreading very much, wide. Filaments white, spreading, longer than the petals. Anthers whitish. In the umbels on the branches most of the florets, and sometimes all are abortive: in the principal umbel a few only in each umbellet: none of these have any germ. Fruit oblong, subcylindric, shining, brownish. Seeds flat and striated on one side, convex on the other with four narrow membranaceous wings, with raised lines between, having a strong smell of Cumin, and an aromatic, subacrid, bitter taste [a].

Native of Austria, Switzerland and France. It flowers in july and august, and the seeds ripen in september. It was cultivated here in 1640, according to Parkinson [b]. Our old authors name it *Sermountain* from the French.

It differs from the varieties of *L. gallicum* in being loftier, in having leaves all along the stem, and the seed longer, with very small membranes, often concealed within the streaks.

The root is extremely bitter, and might be useful in fevers, cachexies, loss of appetite, &c. An infusion of it in wine has been given with success in disorders of the stomach [c]. It yields an aromatic resinous juice on being wounded, and being made into a syrup, is recommended in disorders of the breast [d].

10. Root perennial, striking very deep and but little branched. Stem a foot and half high, terminated by one or two umbels, solid, smooth, slightly striated. Leaves two or three at the base of the stem; and when the stem divides, there is one smaller under the lateral branch, otherwise it is naked: they are four times pinnate, triangular. Leaflets short, lanceolate, a little hard, and loaded with small hairs. Umbels very numerous, convex. Involucres many-leaved, permanent, membranaceous, seldom trifid. Petals white. Fruit oblong, with four wings, which are very narrow [a].

It differs from the seventh species in having the leaves four times divided, with the segments of the pinnules shorter and closer, converging upwards, roughish, and finely hairy on the rib and back of the leaves; the stems commonly simple; the umbel very close; the leaflets of each involucre simple and wider; the petioles round and marked with green and white streaks'.—Native of Switzerland, France, and Italy.

11. Root woody, large, with several forks, crowned with bristles and scales of fallen leaves. Leaves firm, smooth, shining, three times pinnate: leaflets sharply lanceolate, about half a line wide, simple bifid or trifid. Stem-leaves similar, few, more simple. Stem straight, grooved, half a foot high. Umbel very close, globular, convex. Leaflets of the universal involucre seven to ten, mostly petioled, semitrifid, a little shorter than the umbel: those of the partial umbel lanceolate and entire, or trifid. Flower often purple; the petals a little unequal, inflex-cordate. Seed large, ovate, four-winged, often purple or almost black [a].

Native of Switzerland. Introduced in 1775, by Drs. Pitcairn and Fothergill. It flowers in july [b].

12. Leaves entire, cordate, with the upper lobe shorter, crenate, blunt. Petioles very hirsute. Both involucres small. Hence it is different from Pastinaca Opopanax, with which Gouan joins it [a].

Native of Montpelier, where however Gouan could not find any such plant, distinct from P. Opopanax [b].

13. Leaves five times pinnate, extremely superdecompound, very narrow, smooth, lax. Seeds winged [a].

Native of the Levant. Cultivated in 1768, by Mr. Miller. It flowers in june [b].

[a] Jacquin. [b] Morison. [c] Hort. kew. [d] Linn. syst. [e] Jacquin. [a] Seguier.

[a] Jacquin. [b] Haudiquer. [c] Villars. [d] Allion. [e] Villars. [f] Allion. [a] Haller. [b] Hort. kew. [c] Linn. spec. [d] Gouan illustr. 19. n. 2. [a] Linn. spec. [b] Hort. kew.

14. Root perennial, knobbed, and often multiplied at top, ſo as to produce ſeveral ſtems. Leaves deep green, bipinnate like thoſe of Carui, but leſs fine. Stem only two or three inches high, ſlender, upright, ſtriated; terminated by a ſolid, rounded, reddiſh umbel. Leaflets of the involucre trifid; but ſometimes in the partial involucre ſimple. Petals white with a tinge of red. Germ red. The ſeeds have five deep ſtreaks, with as many ribs, without any membranous wing [a].

Native of the mountains of Switzerland, Auſtria, and Dauphiné.

15. Umbels axillary, ſeveral, ſcarcely larger than the petioles [b]. Fruit elliptic-oblong, independent of the wings almoſt cylindric. Seeds having four membranaceous wings, and a raiſed line along the middle of the back, frequently becoming a fifth wing. The wings are of a yellow-bay colour, but the interſtices are ferruginous-brown [c].

Forſter made it a new genus, which he named *Aciphylla* from the ſharpneſs of the leaves like needles.

Native of New Zealand. Found in Queen Charlotte's Sound november 6th, 1774 [d].]

PROPAGATION AND CULTURE.

Theſe plants having no great beauty, and taking up much room, are ſeldom cultivated except in botanic gardens. The roots extend widely; and the leaves of ſome ſorts ſpread three feet, when the plants are ſtrong; the flower-ſtalks riſe four or five feet high, and the umbels of flowers are very large.

Moſt of them are very hardy, and will thrive in any ſoil and ſituation. Sow the ſeeds in autumn, and the plants will come up in the ſpring: but when they are ſown in ſpring, the ſeeds commonly remain in the ground a whole year. Tranſplant them the following autumn where they are deſigned to remain, for they ſend out long deep roots, which are frequently broken by tranſplanting when large. Place them three feet aſunder. The plants decay to the ground every autumn, but the roots continue many years, and require no other culture but to clear them from weeds, and to dig between the roots every ſpring.

The thirteenth ſort requires a warmer ſituation, otherwiſe it will be killed in ſharp winters.

SPECIES.

1. Laſioſtoma Rouhamon.

Lin. ſyſt. ed. Gmel. 248.

Rouhamon guianenſis. *Aubl. guian.* 1. 93. t. 36.

DESCRIPTION, *&c.*

This is a ſhrub with a trunk ſeven or eight feet in height, and ſix or ſeven inches in diameter, with a grayiſh, irregular, rugged bark, and a whitiſh wood. Branches and branchlets oppoſite, covered with a ruſſet down, and ſpreading over the neighbouring trees. The branchlets are knobbed, and at each joint have a pair of leaves, which are entire, ſmooth, oval, ending in a point, and three-nerved underneath; they are of a very pale green, and on very ſhort petioles: the largeſt are two inches long, and an inch four lines in breadth. Flowers in ſmall axillary corymbs, on a ſmall peduncle, which has two ſcales at the baſe: they are oppoſite in pairs, and almoſt ſeſſile. Corolla white. Capſule yellow.

From the axil of the leaves there ſpring at intervals ſimple tendrils, two inches and a half long, curved back in form of a croſs at top, where they become thicker. By means of theſe tendrils the branches ſupport themſelves on the neighbouring trees.

This ſhrub is called *Rouhabomon* by the Caribs. It is in flower and fruit during the months of october and november; and is found on the banks of the river Sinemari in Guiana, forty leagues from its mouth.

A variety occurs with ſmooth branches, larger leaves, ſmaller flowers and fruits. It has no tendrils, but the branches are ſtraight [e].

LATHRÆA. (*From* λαθραιος, *clandeſtinus, which is from* λαθω, *clam.*)

Lin. gen. n. 743. *Reich. n.* 801. *Schreb. n.* 1000. *Gærtn. t.* 52. *Juſſ.* 102.

Clandeſtina. *Tournef.* 424.

Claſſ. 14. 2. Didynamia Angioſpermia.

Nat. order of *Perſonatæ. Pediculares*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, campanulate, ſtraight; *mouth* deeply four-cleft.

COR. one-petalled, ringent. *Tube* longer than the calyx. *Border* ringent, ventricoſe. *Upper lip* concave, galeated, broad, with a narrow hooked tip. *Lower lip* leſs reflex, obtuſe, trifid.

Nectary: an emarginate glandule, depreſſed on each ſide, very ſhort, inſerted into the receptacle of the flower at the other corner of the germ.

STAM. *Filaments* four, awl-ſhaped, length of the corolla, hid under the upper lip. *Anthers* obtuſe, depreſſed, converging.

PIST. *Germ* globoſe-compreſſed. *Style* filiform, length and ſituation of the ſtamens. *Stigma* truncated, nodding.

PER. *Capſule* roundiſh, obtuſe with a point, one-celled, two-valved, elaſtic, coated with a very large ſpreading calyx.

SEEDS few, ſubglobuloſe, affixed to the middle of the valves.

OBS. *It approaches nearly, on account of its glandule, to* Orobanche.

ESSENTIAL CHARACTER.

Cal. four-cleft. *Gland* depreſſed, at the baſe of the future of the germ. *Capſ.* one-celled.

Stem quite ſimple, corollas pendulous, lower lip trifid.

DESCRIPTION, *&c.*

1. Root thick, long, fibrous. Stem half a palm in height, ſurrounded by few, very ſhort, thick, ſharp leaves, and terminated by five, ſix or more naked peduncles, three inches long, each bearing one flower of a blue colour, near two inches in length [a].
The ſtem bears the corymb under ground, ſo that ſolitary fructifications only appear above ground on each branch [b].
Ray and others have this plant twice over.
Native of France, the Pyrenees and Italy. Ray obſerved it in moiſt ſhady places between Maſſa and Lucca.
2. This is a tender juicy plant, a palm and half high. Stem ſurrounded by abundance of ſoft ſucculent leaves, broad at the baſe, and ending in a ſharp point. From the top come out three or four tubular, funnel-ſhaped flowers, an inch or an inch and half in length, of a yellow colour, divided at top into five ſegments [c].
The ſtructure of the flower in this plant is very different from that of Lathræa. The Phelypæa 3. of Linnæus was rightly ſuſpected by Juſſieu to be of a different genus, and it belongs to the genus *Æginetia*. Thunberg has conſtituted a new genus under the name of *Phelypæa*, which Mr. Correa ſuſpects to be a ſpecies of Cytinus.
3. Found by Tournefort in the Levant.
4. Root beaded, branched and ſurrounded with white ſucculent ſcales: it is paraſitical, and generally attached to the roots of Elms, Haſels, or ſome other trees, in a ſhady ſituation. Stem naked, except ſometimes one or two oval ſcales. Flowers in a ſpike, from one ſide of the ſtem, in a double row. Bractes roundiſh-oval, large, reddiſh, one at the baſe of each pedincle, forming a double line oppoſite to the flowers. Calyx hairy, whitiſh, bellying; ſegments equal, bluntiſh. Corolla pale purple or fleſh-coloured, except the lower lip, which is white: the upper lip is rather ſhort and truncate [d].
By this plant and Ophrys Nidus avis we may trace an affinity between Didynamia Angioſpermia of Linnæus, and the natural order of Orchideæ [e].
Native of moſt parts of Europe: with us it is rather rare. Hadlow in Kent. Hareſield in Middleſex. Near Stamford. Woods of Derbyſhire. Conſtick-ſcar near Kendal, Weſtmoreland. Near Gainſford, Durham. In Scotland, at Mevis-bank towards Laſwade, four or five miles from Edinburgh; and in Morvern, near the ſound of Mull.—The flowers appear in april, emerging from the decayed leaves of trees, among which the plant is moſtly found half buried.
The Engliſh name *Toothwort* is derived from the reſemblance of the ſcaly roots, to the human fore-teeth; and hence it was fancied formerly to be good for the tooth-ach [f].
This genus of Linnæus is very miſcellaneous, the ſtructure of the fructification differing widely in the different ſpecies. When theſe ſhall be more accurately examined, perhaps the laſt only may remain in the genus.

Peduncles many-flowered, tendrils many-leaved, ſtipules ovate broader than the leaflet.

DESCRIPTIONS, *&c.*

1. [Root annual, fibrous. Stem from a foot to eighteen inches or more in height, trailing or climbing, four-cornered, ſmooth. Leaves none, except on the young plants, which ſoon after they come up are uſually furniſhed with one or more pair of leaves ſimilar to thoſe of the other ſpecies, but totally diſappearing as the plants advance. Stipules in pairs, large, blunt, on each ſide near the baſe furniſhed with a tooth, glaucous, ribbed on the under ſide, quite entire, ſmooth, larger towards the top of the ſtem. Tendrils ſolitary, ſimple, alternate, horizontal, oppoſite to the pedunckes. Flowers ſmall, ſolitary, axillary. Peduncles longer than the ſtipules, four-cornered, with a minute awl-ſhaped bracte, at the baſe of each flower. Calyx divided almoſt to the baſe: ſegments equal, ſmooth, almoſt as long as the corolla, ribbed. Corolla; ſtandard yellow ſtriped on the inſide with blue lines; wings yellow, nearly round, the length of the keel, with two unequal paler claws; keel pale ſulphur-coloured, cloven behind. Germ ſmooth. Legume an inch in length, broadiſh, flattened; containing ſeven or eight, roundiſh, ſhining ſeeds[a].

Native of moſt parts of Europe, in corn fields, chiefly in light land: flowering in june, july, and auguſt. About Totnenham and Enfield, but not common near London. Between Norwich and Bungay. In Cambridgeſhire not uncommon.

2. *Crimſon Graſs-Vetch* is alſo an annual plant. Stem upright, ſimple, angular, twiſted, ſlightly hairy. Leaves alternate, entire, ſmooth, enſiform, reſembling thoſe of graſſes. Stipules very ſmall, ſpreading, in pairs, at the baſe of the leaves. Tendrils none. Peduncles axillary, ſlightly hairy. Bracte one, ſmall, awl-ſhaped, at the baſe of each flower. Corolla beautiful crimſon. Legume linear, nearly cylindrical, bending downwards, ſmooth or ſlightly downy, terminated by a ſtraight ſtyle[b].

The young plant, before it flowers, is ſo like a graſs, that even an experienced botaniſt might miſtake it for ſuch, eſpecially among mowing graſs, where it uſually occurs; it is alſo found on the borders of corn fields, among buſhes and in woods, but not very common, at leaſt with us, though doubtleſs it is frequently overlooked. Ripton in Huntingdonſhire. Hadnam in Cambridgeſhire. Near Ampthill-park in Bedfordſhire. Coton-field, Stafford. Belmont, Staffordſhire. Hadforwood near Droitwich. About Teignmouth. Near Wick Cliffs. Near London, I have obſerved it about Dulwich, Peckham, Streatham, &c.

Its ſimple graſſy leaves diſtinguiſh this from the other ſpecies. The elegant flowers of a rich crimſon render it deſerving of a place in gardens[c].] Mr. Miller informs us, that ſometimes two flowers are found on one pedunele.

3. This alſo is an annual plant, ſmooth all over. Stem angular, three-ſided at top. Leaves petioled, acute, nerved. The upper petioles have a very ſimple tendril. Stipules linear, ſharp at both ends. Peduncles ſhort. Flowers ſmall, like thoſe of the preceding. Legume ſubcylindric, longitudinally wrinkled, having a long point, toruloſe, with a ſlightly keeled duſky-violet back; containing ten or twelve ſpherical, ſmooth, duſky ſeeds, ſprinkled with darker dots[d].

4. Root annual, fillform, with here and there ovate, feſſile tubercles. Stems ſeveral, weak, ancipital or two-edged. Petioles linear, terminated by a ſlender tendril, with two lanceolate leaflets, and two ovate acute ſtipules having a toothlet at the baſe. Flowers pale purple. Peduncles ſolitary, four-cornered, longer than the leaves. There are other ſtems, deſtitute of leaves, roundiſh, creeping under ground, whitiſh, and bearing flowers and fruit abſolutely perfect, and reſembling thoſe on the ſtems above ground, except that the flowers are ſmaller, and do not expand[e].

Native of the Levant. Cultivated in 1680, in the botanic garden at Oxford[f]. The ſeeds were ſent from Aleppo by Robert Huntingdon, fellow of Merton College[g].

[a] Curtis and Woodward. [b] Woodward. [c] Engl. bot.
[d] Retz. [e] Linn. ſyſt. [f] Hort. kew. [g] Mor. hiſt.

5. In size this takes the middle place between the preceding and following species. Petioles nor membranaceous on the side. Corollas red. Legumes channelled on the back, but not with sharp edges, as in the last and next following sorts. Legumes broad, oval-oblong[a].

Haller thus distinguishes this from *sativus*. The whole plant is lower, but the leaves are larger, broader and elliptic. Peduncles stouter, only half the length, being scarcely four lines long. Flowers only half the size, with a much smaller standard, of a dusky blood-red colour. Legume longer, narrower, rounder, with a short vestige of wings on the back, and a groove between. Seeds four.

Root annual, simple. Stems several, from a foot to two feet in height, simple, angular, winged, procumbent unless supported by other plants. Petioles from half an inch to an inch and more in length, coming out at intervals from an inch to two inches, at an acute angle with the stem, consisting of a nerve with two membranes on each side: each of these produces two grass-like lanceolate-linear leaves, from one inch to four inches in length, and from two to six lines in breadth, three-nerved and smooth: nerve of the petiole produced about an inch beyond the leaf, ends in a tendril usually trifid. At the base of the petiole two stipules, large in proportion to the plant, smooth, frequently as wide as the leaf, seldom wider, broad-lanceolate, from a broad base putting out downwards an ear or hook with one or two teeth. From the axils of these stipules, almost the whole length of the stem arise stout peduncles, not winged, the shortest half an inch long, longer towards the upper part till they attain the length of an inch and more: about the middle or rather nearer to the flower they have two very slender bristles, and they are bowed by the weight of the growing legume. Flower of a middling size. Calyx smooth; segments a little unequal, the two upper approximating, lowest narrower and longer. Corolla white or pale yellow, or red and white, very seldom blue, sometimes quite red or deep purple. Legume from one to two inches long, broad, compressed, difform, ovate-oblong, smooth, netted-veined, terminated by the permanent style, having two wings running along the back. Seeds three, four or five, smaller than peas, tawny with dots of a deeper colour, angular, difform[b].

Native of France and Spain. Cultivated here in 1633. It flowers in june and july.

6. The habit of this is the same. The root also is not different. Leaves longer, narrower. Stipules of the same shape, but commonly only half the width. Peduncles from one to two inches long, weaker, but having two bristles as that has. Flower double the size, most commonly white, sometimes tinged with purple, or having a rose-coloured standard, or blue, or blue and white variegated. Legumes broader, shorter, with the wings on the back more apparent, insomuch that the groove between them is of considerable depth. Notwithstanding these differences, this and the preceding are perhaps no more than varieties[c].

In our gardens it is distinguishable by the blue colour of the corolla, but we have sometime the milk-white variety. The seed-pods afford a more certain mark of distinction, being unusually short, broad, and winged on the back[d].

Native of France and Spain; commonly sown in Switzerland for soiling horses, but not indigenous of that country. The French name is *Gesse*. It flowers in june and july; and was cultivated in 1739, in the botanic garden at Chelsea[e].

In several parts of the Continent a white, light pleasant bread is made from the flour of this pulse, but it produced such dreadful effects in the last century, that the use of it was forbid by an edict of George Duke of Wirtemberg in 1671; and this not being observed was inforced by two other edicts under his successor Leopold, in 1705 and 1714.

Mixed with Wheat flour in half the quantity, it makes a very good bread, that appears to be harmless. But bread made with this flour only has brought on a most surprising rigidity of the limbs in those who have used it for a continuance; insomuch that the exterior muscles could not by any means be reduced, or have their natural action restored. These symptoms usually appeared on a sudden, without any previous pain; but sometimes they were preceded by a weakness and disagreeable sensation about the knees.

Baths both hot and cold, fomentations and ointments of various kinds have been tried without effect; insomuch that it is regarded as incurable, and being neither very painful nor fatal, those who are seized with it usually submit to it with patience.

Swine fattened with this meal lost the use of their limbs, but grew very fat lying on the ground. A horse fed some months on the dried herb was said to have his legs perfectly rigid. Kine are reported to grow lean on it, but sheep not to be affected. Pigeons, especially young ones, lose the power of walking by feeding on the seed. Poultry will not readily touch it, but geese eat it without any apparent damage. In some parts of Switzerland cattle feed on the herb without any harm. It would be worth enquiring therefore whether the soil may not contribute something to the ill qualities of the plant: and it is remarked that the seed from a strong, fat, moist soil, is much more deleterious than from a light dry one[f].

Fabbroni from Florence in 1786 says that the government there has cautioned the peasants against the use of Lathyrus sativus, swine having lost the use of their limbs, and become pitiable monsters by being fed on this pulse exclusively. The peasants however eat it boiled, or mixed with wheat flour, in the quantity of one-fourth, without any harm.

The poisonous Lathyrus from Barbary is L. semine punctato of Cafp. Bauhin, and seems to be only a variety; for in the crops of L. sativus in Italy they find black seeds striped with white, as in the African seed. Fabbroni suspects it to be a mule between L. sativus and Cicera, for the flower and seed partake of the characters of both; having a black seed marked with white, and a white banner with a red keel to the corolla[g].

7. This is a small plant, a span or at most a foot in height. Stems obscurely triangular. Stipules subulate-lanceolate, with the hinder tooth acute. Petioles very short; the lower terminated by a very short awl-shaped bristle; the upper elongated into a filiform tendril. Leaflets striated underneath, and acuminate. Calyx very small and shorter than the stipules from the axils of the petioles on a scarcely apparent peduncle. Corolla scarcely longer than the calyx, pale. Legume almost the length of the leaves, but broader, smooth, stiff and straight[h].

Root annual. Stems several, weak, a foot or eighteen inches in height. The whole plant smooth. Leaflets either ensiform, or narrow lanceolate, with three or five nerves underneath. Stipules almost as long as the petioles, with the lower hook much shortest, and a minute toothlet in the middle. Peduncles axillary, solitary, in some individuals shorter than the calyx, in others twice or thrice as long, terminated by a bristle, which also varies in length. Standard and wings of the corolla deep red; keel pale. Legume linear, veined, acuminate, scarcely compressed, containing eight seeds at most, which are dusky and rounded-angular[i].

Native of the Levant. Cultivated by Mr. Miller in 1739[k].

Monf. Villars says that it is found wild in Dauphiné; where they have also another Lathyrus with one-flowered peduncles, which he names *bicuritus*, on account of the two-eared stipules, broader than the leaves. The stems are straight and quadrangular: the leaves linear-lanceolate and conjugate: the legume oblong, containing six seeds.

8. Gerard thus distinguishes this from the next.

[a] Linn. spec. [b] G. D. Duvernoy Thesis, 1770.
[c] Duvernoy thes. [d] Curtis. [e] Hort. kew.
[f] Duvernoy. [g] Fabbroni's letters in M.S.S. Banks.
[h] Linn. spec. [i] Jacquin. [k] Hort. kew.

The ſtem is ſimple or at moſt double, ſubſolitary as Linnæus calls it, longer, procumbent, almoſt naked. Leaflets ſetaceous, narrower, with the nerves not ſo conſpicuous. Stipules linear, with a longer appendicle. Petiole thrice the length of the ſtipule. Legume ſubovate, turgid. Seeds two or three, ſpherical, very ſmooth.

About Montpelier, on monte Baldo, Italy. Cultivated in 1739 by Mr. Miller [1] who deſcribes it as an annual plant, ſeldom more than ſix or eight inches high, with bright ſcarlet flowers.

[9. This is an annual plant as well as the laſt; but it produces many ſtems, which are diffuſed, a ſpan long, with the internodes approximating. Leaflets linear, gradually longer and narrower, nerved. Stipules lanceolate. Petiole about the ſame length with the ſtipule. Legume oblong, broadiſh, compreſſed, a little curved in at the tip. Seeds five or ſix, angular [2]

Allione has given a new ſpecies under the name of *L. coccineus*, which he diſtinguiſhes from this, by its ſcarlet flowers, lanceolate leaves with five nerves, and a nerved torofe legume, not compreſſed and broad, as in that, and containing a greater number of ſeeds, which are nicely round, not angular [3].

He gives the ſame ſynonym of Ray, which Duvernoy aſſigns to *L. Cirrea*, n. 5. and that of Seguier, which Linnæus and others give to *ſetifolius*. Gerard ſays, that all the ſynonyms of *angulatus* are uncertain, except thoſe of Tournefort, Magnol and Buxbaum.

10. The leaves have uſually four leaflets; the lower petioles are lanceolate and leafleſs. Stipules mucronate at both ends. The flower has the keel of the Pea, waved on the ſides, and not oblique as in Lathyrus. Standard bright red, with white wings and keel [4]. Legume oblong, narrow, attenuated to both ends, compreſſed, ſwelling over the ſeeds. Peduncles of the ſeeds forked. Seeds four, elliptic lens-ſhaped, ſmooth, clouded with aſh-colour and brown [5].]

Miller ſays, it is an annual plant with a climbing ſtalk which riſes near three feet high; that the leaves have ſeveral leaflets, terminated by very long claſpers; that the peduncles are five or ſix inches long, with two flowers, one above another; that it flowers in june and july, and the ſeeds ripen in autumn.

[Native of the South of Europe. Cultivated in the botanic garden at Cheliea, in 1739 [6].]

11. The *Sweet Pea* as it is commonly called, is an annual plant, which riſes from three to four feet high, by means of its long claſpers or tendrils. The flower-ſtalks come out at the joints, are about ſix inches long, and ſuſtain two large flowers, which have a ſtrong odour; and are ſucceeded by oblong hairy pods, having four or five roundiſh ſeeds in each.

In the common ſort the corolla has dark-purple ſtandards, with the keel and wings of a light blue. (variety *b*.) Other varieties are the white; the pink with a white keel, and the wings pale bluſh-colour; [the pink or bluſh-coloured ſtandard with both keel and wings white; the roſe-coloured ſtandard with the wings and keel pale blue: theſe that have a mixture of red with white or pale blue are called Painted Ladies. There is alſo a variety of the common dark ſort, with the keel pale violet, and the wings dark violet, &c.

According to Linnæus the common dark ſort is a native of Sicily, and the painted Lady of Ceylon. This flower now become ſo common was not known to our gardens in the time of Parkinſon or Evelyn. It was cultivated by Dr. Uvedale at Enfield in the year 1700 [7]. Mr. Petiver obſerved it there with Dr. Plukenet, and afterwards at Cheliea and elſewhere. He inſerts it in his liſt of rare plants obſerved in 1713 [8].]

12. This riſes with a climbing ſtalk five or ſix feet high, having two membranes or wings running from joint to joint. Leaflets long and narrow. Peduncles long, each ſuſtaining two pale-yellow flowers, which are ſucceeded by long taper pods, containing ſeveral roundiſh ſeeds.

[It has the appearance of the larger perennial *Lathyri* with yellow flowers, but differs in being annual, whence Linnæus gave it the trivial name of *annuus*, which is otherwiſe improper, all the ſpecies of the two firſt diviſions, except the thirteenth, being likewiſe annual. The ſtem is angular and lofty, the leaflets ſmooth, and three times as long as the common petiole, which has two linear ſemiſagittate ſtipules at its baſe, about half its length, and briſtles in three twiſted tendrils. The peduncles commonly bear only one ſmall yellow flower, and end in a ſort of awn. Legume long, containing nine ſeeds [9].

Linnæus deſcribes the ſtipules as two-parted, very narrow, with the upper ſegment awl-ſhaped, the lower linear and even almoſt capillaceous.

Native of France and Spain.] Mr. Miller, ſays he has alſo received the ſeeds from Siberia. Cultivated in 1640, by Mr. John Coys, according to Parkinſon [1].

13. Stem woody, two feet high, much branched. Branches round, tomentoſe, hanging down. Leaves alternate. Leaflets about twenty pairs or more, ovate, white underneath, reflex at the edge, ſubſeſſile. Stipules awl-ſhaped, ſhort, deciduous, tomentoſe, inſerted into the petiole. Flowers axillary, on ſhort, white-tomentoſe peduncles, with one bractle to each flower. Calyx globular. Corolla yellow. Legume oblong, ſtraight, hanging down, narrower at the baſe, ſubtomentoſe; containing from eight to ten obovate ſeeds.

Native of Peru, on the hills near Huanuco. Cultivated in the royal garden at Madrid before 1791, and flowering there from july to november.

It has the habit of *Orobus* with the ſtyle of *Lathyrus* [2].]

14. Stem four or five feet high. Leaflets veined. Peduncles ſhort, ſuſtaining two large flowers with purple ſtandards, the wings and keel bright red. Legumes long, jointed; containing ſeveral ſeeds.

[The whole plant is very ſmooth. Stem branched, running out on each ſide into a ſlender ſharp wing. Petioles angular, ending in bifid, trifid or ſimple tendrils. Stipules lanceolate, acuminate, produced downwards into an earlet, ſimilar but much ſmaller. Peduncles ſometimes one-flowered. Calyx under the banner purple. Keel much ſhorter and narrower than the wings. Legume browniſh, ſwelling over the ſeeds, which are ſix or ſeven in number, ſcarcely angular, and variegated with black and brown [3].

Native of Barbary. Cultivated in 1680, by Robert Moriſon, M. D. [4] who had the ſeeds from Tangier by Alexander Balain, Conſul there; and afterwards by Robert Spotſwood, Surgeon at the ſame place. It flowers in june and july; and although it has not the agreeable ſcent, or variety of colours, or continuance in blow of the Sweet Pea, yet it is uſually ſown in our gardens with other annuals [5].

15. Native of the Levant.]

16. Root perennial (all other authors ſay annual). Stalks three or four, weak, near two feet long. Peduncles about four inches in length, ſuſtaining two purple flowers, (frequently three). Pods rough, little more than an inch long, containing three or four roundiſh ſeeds.

[Stems angular, twiſted, ſlightly hairy. Leaflets ſlightly hairy, with three ſtrong ribs, terminated by an awn. Petioles triangular, furrowed above. Tendrils moſtly dividing into three. Stipules ſemiſagittate, pointed, with long appendages, two at the baſe of each petiole. Flowers an inch or an inch and half from each other. Bractes awl-ſhaped, ſmall, about a quarter of an inch beneath the terminating flower, and at the baſe of the ſhort pedicel of the lower. Calyx one-third of the corolla in length; ſegments equal, extending half way down. Corolla purple, with yellow lines within. Legumes ſhort, covered with hairs, each hair proceeding from a gland [6].

Native of many parts of Europe. With us not common.] Mr. Miller found it in places ſpread over with brambles near Hockley in Eſſex. [It has been obſerved in ſeveral parts of that county, as about

Hockley

Hockley and Raleigh, and elſewhere in Rochford hundred; near Munden-church and Laydon-hall in Dengy hundred. On hills north of Penſford, on the Briſtol road, and between Penſford and Keynſham in Somerſetſhire. It flowers in july.]

17. Root creeping, putting out irregular tubers about as big as thoſe of the Pig-nut, covered with a brown ſkin. Theſe ſhoot up ſeveral weak, trailing ſtalks. Pedunckes weak, about three inches long, each ſuſtaining two flowers. Corollas deep red.

[Stems about a foot high, obſcurely quadrangular, branched, ſmooth. Leaves alternate, petioled; leaflets ſubſeſſile, acuminate, ending in an awn, bright green, very ſmooth, involute. Stipules ſagittate, quite entire. Peduncles axillary five or ſix-flowered. Legume long, containing ten or twelve ſeeds *.] Theſe are ſeldom produced in England. This plant is cultivated in Holland for the roots, is ſold in the markets and commonly eaten there. [With us only for ornament, being a beautiful hardy perennial, reſembling the Everlaſting Pea, but of an humbler growth. It ſhould however be introduced with caution, on account of its creeping roots, and is perhaps better ſuited to the unclipped hedge of the pleaſure-ground, than the border of the flower-garden †.

Native of France, Germany, Flanders, Holland, Switzerland, Auſtria, Siberia. It flowers in july and auguſt; and was cultivated in 1640 by Parkinſon ‡, who calls it *Peaſe Earth-Nut*, as does alſo Gerarde.

18. Root perennial, creeping. Stems a foot or eighteen inches, and ſometimes three feet or even more in length, when without ſupport procumbent, but climbing by means of tendrils, and having the appearance of being upright in meadows, and eſpecially among buſhes; they are obtuſely quadrangular, and much branched. Leaflets quite entire, ſmooth or ſlightly villoſe underneath only, marked with three nerves, on triangular, furrowed peticles. Stipules in pairs, large, ſhaped like the head of a halbert, or half the head of an arrow, frequently having ſharp proceſſes at the baſe. Flowers in a raceme, directed one way, from four or five to eight or ten, on axillary pedunckes, four or five inches long, four-cornered: each on a hairy pedicel, with a very minute awl-ſhaped bracte at the baſe. Calyx one-third of the length of the corolla, divided half way into five awl-ſhaped ſegments, which are rather unequal, and ſomewhat hairy. Corolla yellow. Legumes an inch and half long, compreſſed, ſmooth, black, containing from ſeven or eight to twelve globular ſhining ſeeds, of a yelloviſh or brown colour, with ſmall purple dots.

Native of moſt parts of Europe, in meadows and paſtures, woods, thickets and hedges, flowering from june to auguſt.

According to Linneus, horſes, kine, ſheep and goats eat it. Swine refuſe it: and the Badger is ſaid to feed upon it.

In old authors this plant is much reprobated as a vile weed, that ſpreads much by means of its creeping roots, and accordingly Mr. Miller will not have it admitted into gardens. Many modern writers however recommend it as an excellent food for cattle, and not without reaſon, ſince its quality is good, and it bears a large burden of ſucculent leafy ſtalks. Among its patrons we may reckon Linneus, Haller, Schreber, Anderſon, Curtis and Young.

Mr. Swayne aſſerts, that it does not ſeem to be at all agreeable to cattle, and that where they have a choice of feed they ſeldom touch it. But with reſpect to this and many other leguminous plants, we are not to conclude that they are diſagreeable to cattle, becauſe they are not eaten in their fruiting ſtate. They may ſtill be exceellent in hay, and the cattle may be fond of the young ſucculent herbage. This, and other leguminous plants are beſt mixed with good graſſes in permanent meadows. Mr. Curtis informs us that he obſerved a piece of ſtiff ſoil, belonging to Lord Loughborough, near Mitcham, which produced an excellent crop, conſiſting chiefly of this plant, and Feſtuca pratenſis. There could not well be a better mixture than this made by art, for ſtrong land.

A difficulty which Mr. Swayne mentions is not ſo eaſily got over. This is, that it produces very few ſeeds, and that thoſe few are for the moſt part devoured by a ſpecies of Curculio. Probably with care in a garden, a ſufficient quantity of ſeed might be produced; or if not, we muſt have recourſe to the ordinary methods of increaſing perennial plants, by the roots, layers or cuttings.

It is called in Engliſh, Common yellow or meadow Vetchling, and Tare Everlaſting.

19. Root perennial. Stems ſix feet or more in height, climbing or trailing, ſpreading widely, branched, winged and ſmooth. Leaves petioled: leaflets ending in a ſhort point, beneath three-ribbed, glandular at the baſe. Petioles three-ſided, winged, rough at the edge. Tendrils for the moſt part trifid. Stipules linear-lanceolate, half-arrow-ſhaped or awl-ſhaped, very narrow, hooked, or bearded at bottom. Peduncles a ſpan long, ſomewhat angular, naked; with one awl-ſhaped bracte at the baſe of each pedicel, which is ſhort, bending and coloured. Flowers not more than ſix in a raceme. Corolla red and white: ſtandard large, roſe-coloured, faintly netted-veined; wings violet; keel whitiſh green. Legumes two inches long, and nearly half an inch wide, compreſſed, ſmooth, brown. Seeds ten to twelve, nearly round, blackiſh *.

This is diſtinguiſhed from *latifolius* by the leaves not being broader than the ſtem and three-ribbed, and the flowers of a much ſmaller ſize *.

Native of moſt parts of Europe. In England, between Caſtle Camps and Barrlow in Cambridgeſhire. Between Bath and Briſtol. Conway in Wales. Between Perthore and Eckington in Worceſterſhire. Shelton bank near Salop. Near Penſford, &c. Near London it is rare, in the Oak of Honour wood near Peckham. In many parts of Kent and Bedfordſhire it grows abundantly.

Though greatly inferior to L. latifolius, it is however frequently ſeen in gardens.

20. Root perennial. Stalks ſeveral, thick, climbing by means of tendrils to the height of ſix or eight feet, or even higher in woods: theſe die to the ground in autumn, and new ones riſe in the ſpring from the ſame root. Leaves ſtiff, marked with three or five ſtrong ribs, rolled in at the edge, blunt at the end, but terminating in a little point or briſtle; they are always in pairs, and on a winged petiole; at the baſe of this are large ſtipules, ſhaped ſomewhat like the head of a halbert. Tendrils multifid or branched. Peduncles eight or nine inches long. Each flower has an awl-ſhaped bracte at the baſe of the pedicel. Corolla pale purpliſh roſe-colour. Legumes an inch and half long, and half an inch in breadth.

This ſpecies is diſtinguiſhed from the narrow-leaved ſort (L. ſylveſtris) by the greater breadth of the leaves, and by the abundance and ſuperior ſize of the flowers.

Native of many parts of Europe, in hedges and woods. Mr. Ray obſerved it about the middle of the laſt century in the Cambridgeſhire woods, and it ſtill keeps its poſt, though almoſt a century and half has elapſed. Johnſon in Gerarde ſays, that great ſtore of it grows in Swainſcombe wood near Greenhithe in Kent. Rocks near Red Neeſe by Whitehaven. Severn Stoke Copſe, Worceſterſhire, &c. It flowers at the end of june and beginning of july.

It is a ſhowy plant for ſhrubberies, wilderneſs quarters, arbours, and trellis-work; but too large and rampant for the borders of the common flower-garden. Bees reſort much to it, and the flowers furniſh them with abundance of honey. It yields a great quantity both of green fodder and ſeeds; but in what degree the former might be agreeable to cattle, and the latter to pigeons or poultry, muſt be ſeen by experience.

21. Root perennial. Stems quadrangular, winged, two wings broader, three or four feet high. Leaflets nerved, ſhorter than thoſe of *L. ſylveſtris*, and longer than thoſe of *L. latifolius*. Petioles triangular, longer

* Pollich. † Curtis.
‡ Hort. kew.

* Curtis. * Withering.

than the leaves. Tendrils branched. Stipules lanceolate, scarcely wider than the ſtem. Flowers in racemes of about ſix together. Standard and wings fleſh-coloured; keel whitiſh.

By the leaves, the wings of the ſtem, and the ſize of the flowers, this is a ſpecies intermediate between *ſylveſtris* and *latifolius*[3].

Native of Sweden, Switzerland, France, Sileſia.

22. Root perennial, creeping. Whole plant ſmooth. Stems from three to four feet high when ſupported, but little branched, winged. Leaflets two or three pairs, oppoſite or rarely alternate, lanceolate, acute, glaucous beneath. Tendrils two-cleft or three-cleft. Stipules half-arrow-ſhaped. Flowers three, ſometimes to ſix or more, pointing one way, in erect racemes. Corolla vivid purpliſh blue, of great beauty. Legumes longiſh and ſmooth[4].

The wings of the ſtem are narrower than in *ſylveſtris*. The figure in Flora Danica repreſents thirteen flowers, rather red than blue.

Native of many parts of Europe, in moiſt woods and paſtures, but in England not common. Peckham-field on the back of Southwark; found by Thomas Williſel. Wood near Abingdon. Near Ranaugh and Burgh in Norfolk. Little Everſden and Bardwell ſens in Cambridgeſhire. Eaſt Fen, Lincolnſhire. Bardon hill, Chorley foreſt in Leiceſterſhire. Lancaſhire. Yorkſhire. Scotland.

23. Root perennial. Plant growing like the Pea. Stems acute-angled. Petioles often ſix-leaved (ſometimes eight). Leaflets ovate-oblong, acute. Stipules acuminate at the baſe, ſcarcely angular. Peduncles the length of the leaves. Corolla with the ſtandard and wings whitiſh with purple veins (Miller ſays blue). Standard ſmall, with the keel of Pea, and not oblique. Style longitudinally bearded above.

The leaflets are convolute as in *Piſum maritimum* and *Ochrus*; not involute, as in moſt of the *Lathyri*[5].

Native of Germany and Siberia. Cultivated by Mr. Miller in 1759. It flowers in june[6].

Lathyrus pariſienſis of Miller, n. 4. is different from all the above. It belongs to the firſt diviſion, having one-flowered peduncles.] He deſcribes it as an annual plant, with a ſlender ſtalk, about a foot high. Leaves compoſed of ſeveral narrow leaflets, placed alternately. Stipules lanceolate. The flowers come out ſingly upon pretty long peduncles: they are blue, and about the ſize of thoſe of Common Tare.

[From his ſpecimens in the Bankſian herbarium, which came from the Paris garden, it appears that the leaflets are often in two pairs, but that the number varies exceedingly from one to ſix or ſeven. Some of the tendrils are ſimple, others branched. The ſtem is winged, and the rachis of the leaves remarkably ſo. It has a glaucous hue. Miller ſeems to have confounded it with our L. paluſtris, from which it is very different.

L. magno flore, n. 14. figured in t. 160. of the figures, is nothing more than a variety of L. latifolius.] He ſays it differs from that in having much ſhorter ſtronger ſtalks; broader leaves of a deeper green; much larger flowers of a brighter red colour.

[Of Mr. Miller's laſt Lathyrus I know nothing. He calls it L. americanus; it is one of Houſtoun's plants found at La Vera Cruz, and belongs to the ſecond diviſion, having two-flowered peduncles.] It is an annual plant, with a trailing ſtalk a foot long; a ſingle kidney-ſhaped leaf, veined beneath, at each joint; peduncles very ſhort; flowers ſmall, of a deep yellow colour; ſucceeded by ſhort taper pods, including three or four ſmall roundiſh ſeeds. Houſtoun names it Niſſolia americana procumbens, folio rotundo, flore luteo.

PROPAGATION AND CULTURE.

Theſe may all be propagated by ſowing their ſeeds, either in ſpring or autumn; but thoſe which are ſowed in autumn ſhould have a light ſoil and a warm ſituation, where the plants will abide the winter, and come to flower early the following ſpring, and their ſeeds will ripen in july; but thoſe which are ſown in the ſpring ſhould have an open expoſure, and may be planted upon almoſt any ſoil, if not too wet, for they are not tender plants, nor do they require much culture: theſe ſorts ſhould all of them be ſown where they are deſigned to remain, for they ſeldom ſucceed when they are tranſplanted, unleſs it is done while the plants are young; ſo that where they are ſown for ornament, there ſhould be four or five ſeeds ſown in a ſmall patch, in different parts of the borders of the flower-garden; and when the plants come up, they ſhould be carefully kept clear from weeds; but when they are grown two or three inches high, there ſhould be ſome ſticks put down by them to ſupport them, otherwiſe they will trail on the ground, or on whatever plants ſtand near them, and become unſightly.

The eleventh ſort, with the varieties of it, are deſerving of room in every good garden for the beauty and odour of their flowers; and the fourteenth ſort is by ſome cultivated for the colour of the flowers; but there are few of the other ſorts worthy of room in gardens, except the twentieth ſort, which, if it be planted in a proper ſituation, and rightly trained, will make a fine appearance.

[6. The ſeeds of L. ſativus are ſown, in the countries where it is cultivated for fodder or the ſeed, at the end of auguſt, the beginning of ſeptember, or in the ſpring; in ſtrong ground: for in a light dry ſoil the roots are very weak, and it is apt to be deſtroyed by ſpring froſts. Its produce is very abundant, and the culture not being expenſive is very general in ſome parts of Europe.

11. The gardeners, who raiſe Sweet Peas for the London markets, ſow them in the autumn in pots, and ſecure them from ſevere weather by placing them in hot-bed frames; by which means they can bring them early to market. They may be continued in flower the whole ſummer by repeated ſowings in the ſpring. When ſown in pots they muſt be watered frequently.

17. Tuberous Lathyrus is as noxious a weed to the huſbandman as ſmall Bindweed (Convolvulus arvenſis), and equally difficult to extirpate. The tubers of the root are in high eſteem in ſome countries as an article of food, and the plant is eaſily propagated either by theſe or the ſeed. With us the former method only can be practiſed. It thrives beſt on light ground.

Leaves petioled ovate-cordate ſerrate fleſhy, ſpike four-cornered, calyxes recurved.

DESCRIPTIONS, *&c.*

1. Root perennial, thick, woody. Stem ſhrubby, much branched, frequently five or ſix feet high, four-cornered, acute-angled, tomentoſe. Leaves numerous, blunt, hoary, the upper ones ſeſſile, the lower petioled. The flowers are produced in terminating ſpikes from the young ſhoots, on long peduncles; the ſpikes are compoſed of interrupted whorls in which the flowers are from ſix to ten, the lower whorls more remote. Each flower upright, on a ſhort pedicel. Bractes broad-ovate, awned, acuminate, veined. The common colour of the corolla is blue, but it varies with white flowers. The whole plant is covered with a down compoſed of forked hairs[a].]

β. Broad-leaved Lavender has much ſhorter and broader leaves, and the branches are ſhorter, more compact, and fuller of leaves. It will continue ſeveral years without producing flowers; and when it does, the leaves on the flowering ſtalks approach nearer to thoſe of the common Lavender, but are ſtill broader. The ſtalks grow taller, the ſpikes are looſer and larger, the flowers ſmaller, and appear a little later in the ſeaſon.

[Gerard obſerves, that this variety has not only broader leaves, but two oppoſite branches at the bottom of the ſtem, and paler-coloured flowers. This alſo varies with the corolla entirely white.

Native of the South of Europe, on mountains, by way ſides, and in barren places: Aſia and Africa. It flowers here from July to September, and was cultivated in 1568, as appears from Turner[b].

Lavender is a plant which has long been celebrated for its virtues in nervous diſeaſes. According to Dr. Cullen it is, "whether externally or internally, a powerful ſtimulant to the nervous ſyſtem; and amongſt others of this order, named Cephalics, the Lavender has a very good, and perhaps, the beſt title to it." And he farther ſays, "it appears to me probable that it will ſeldom go farther than exciting the energy of the brain to a fuller impulſe of the nervous power into the nerves of the animal functions, and ſeldom into thoſe of the vital. It may however be with great propriety, that Profeſſor Murray has diſſuaded its uſe where there is any danger from a ſtimulus applied to the ſanguiferous ſyſtem. It is however ſtill probable that Lavender commonly ſtimulates the nervous ſyſtem only, and therefore may be more ſafe in palſy than the warmer aromatics, eſpecially if the Lavender be not given in a ſpirituous menſtruum, or along with heating aromatics, which however is commonly done in the caſe of the ſpiritus Lavandulæ compoſitus.

The officinal preparations of Lavender are the eſſential oil, a ſimple ſpirit, and a compound tincture. The eſſential oil has been uſed for ſtimulating paralytic limbs, and for ſeveral external purpoſes.]

2. French Lavender or purple Stœchas has a low, thick, ſhrubby ſtalk, about two feet high, ſending out woody branches the whole length. Leaves about an inch long, hoary and pointed, of a ſtrong aromatic ſcent, oppoſite at each joint, with ſmaller leaves of the ſame ſhape coming out at the ſame places. The branches are terminated with ſcaly ſpikes of purple flowers, four-cornered, and an inch in length; and at the top a coma or ſmall tuft of purple leaves. The whole plant has a very ſtrong, aromatic, agreeable odour.

[Stem obſcurely, branches acutely quadrangular. Leaves quite entire, with a longitudinal groove at top, beneath tranſverſely veined, wrinkled. Spike on a ſhort peduncle. When it begins to flower, there are only four flowers in a whorl, but theſe are afterwards increaſed by the lateral gems, till it becomes gradually round. The bractes are broad-ovate and ſubtrilobate, with the middle lobe more produced; they are ſubtomentoſe, purple, and veined: at the top they widen into larger, oblong, violet-coloured leaves, and form a coma[c].]

[a] Linn. diff. [b] Hort. kew. [c] Linn. diff.

β. The peduncles in this variety are three times the length of thoſe in the common Stoechas, and naked. The ſpikes are longer and not ſo thick, and the leaves of the coma are more numerous, longer, and of a brighter purple colour. Both theſe vary to purple, and white in the corolla, but the moſt common colour is blue.

[Native of the South of Europe. Cultivated in 1568, according to Turner. It flowers from may to july.

3. This differs from the preceding by its wrinkled villoſe leaves, which are green, and not hoary, as in that; the bractes alſo and coma are green and entire, not purple and ſubtrilobate, as in L. Stoechas.

Found in the iſland of Madeira by Maſſon [d]. Introduced in 1777. It flowers from may to july [e].]

4. This has a woody ſtalk two or three feet high, with four-cornered branches on every ſide the whole length. Leaves oppoſite, about an inch long, and an eighth of an inch broad, indented regularly on both ſides almoſt to the midrib, of a grayiſh colour, a pleaſant aromatic odour, and a biting warm taſte. The flowers are produced in ſcaly ſpikes at the ends of the branches upon long naked peduncles. The ſpikes are four-cornered, hairy, and about an inch long, terminated by a few purpliſh leaves.

[Stem hiſpid, with the angles prominent, rounded, having a groove on each ſide. Leaves hiſpid with hairs inſerted into raiſed points: leaflets linear, ſhort, truncate. Peduncle quadrangular, tomentoſe. Bractes broad-ovate, rounded at top, hiſpid, coloured, veined; the terminating ones larger and of a darker colour [f].

Native of Spain and the Levant. Cultivated in 1597, as appears from Gerarde. It flowers from june to ſeptember [g].

5. This is a low, very branching ſhrub, with a browniſh bark. Younger branches quadrangular, but becoming round as they grow woody. Leaves very blunt, thickiſh, ſoft to the touch, oppoſite, hoary: leaflets oblong, ſometimes quite entire, ſometimes bifid or trifid at top. Petioles channelled, the lower ones very long. Peduncles leafleſs, about a foot in length, upright, ſoft, hoary, quadrangular at top. Spikes commonly three together, upright, obtuſely quadrangular, lanceolate, acute. Bractes ovate or lanceolate, concave, quite entire, upright, ſilky, a little longer than the calyx; in the fruiting plant ſquarroſe. Calyx pale green or hoary. Corolla purple or pale violet, with a hairy throat, an upright tube twice the length of the calyx, and the upper lip double the length of the lower. Anthers round, villoſe. Stigma purpliſh. Seeds ſmall, oblong, black with a white ſcar. The flowers have a ſweet ſmell; but the leaves have very little ſmell or taſte [h].

Native of Madeira, where it was found by Mr. Francis Maſſon. Introduced in 1777. It flowers from april to october [i].]

6. This is an annual (or rather a biennial) plant, with an upright branching woolly ſtalk two feet high. Leaves hoary, oppoſite, cut into many diviſions to the midrib: theſe ſegments are again divided on their borders towards the top into three blunt ones, ſo that they end in many points. The peduncle is continued from the end of the branch, is naked, and about ſix inches long, quadrangular, and terminated by a cloſe ſpike of flowers about one inch long: the rows of flowers are twiſted ſpirally. There are commonly two ſmall ſpikes below this, and about an inch from it. The corolla varies from blue to white.

[Stem quadrangular, with the angles acute and extremely villoſe. The leaflets have four or five ſegments (three on the upper and one or two on the lower) lanceolate, blunt. The lower leaves are petioled, the upper ſeſſile; all flat and hairy; the uppermoſt have a few ſimple hairs, and more that are compound, always moiſt and ſomewhat clammy with the oil that exudes from them. Peduncle tomentoſe. Spike lanceolate, quadrangular, gradually lengthened whilſt the flowers open, becoming cylindric, but with four ſpiral angles. Bractes lanceolate, hoary, ſhorter. Flowers four in a whorl. Corolla violet-coloured [k]. Seeds roundiſh, ſmall, bay-coloured, convex on one ſide, obſcurely angular on the other, obliquely truncate at the baſe, and marked with a very wide white umbilical area [l].

Native of Spain. Cultivated in 1597, as appears from Gerarde [m].]

β. This riſes with an upright branching, ſquare ſtalk, four feet high. Leaves longer, and cut into narrower ſegments than the Spaniſh plant: they are of a lighter green, and almoſt ſmooth: the naked flower-ſtalk is alſo much longer, and terminated with a cluſter of ſpikes of blue flowers; at two or three inches below theſe are two ſmall ſpikes, one on each ſide. The flowers are ſmaller than thoſe of common Lavender.

Native of the Canary iſlands, whence the ſeeds were ſent to Compton Biſhop of London, in whoſe garden at Fulham the plants were firſt raiſed.

[7. Stem quadrangular, with the angles rounded, ſcarcely pubeſcent. Leaves veined, very finely pubeſcent, deciduous in the time of flowering; on petioles the length of the leaves, horizontal, ſemicylindric, channelled. Spike at firſt pyramidal and four-cornered, dilated and becoming round during the time of flowering, but when the germs are fecundated elongated into a cylinder. Bractes fleſhy, hairy, ciliate, acute, erect. Flowers four in a whorl, recurved. Corolla blue. The fruiting ſpike reſembles a cylindric ſtrobile, with recurved ſcales.

This ſpecies does not coaleſce kindly with the reſt; but the bilabiate calyx and the reſupine corolla evidently place it here [n].

Native of the Eaſt Indies, (where it was obſerved by Koenig near Sadraſs on very arid rocks and walls, and by Rheede in the ſands of Malabar). It was introduced in 1778 by the Right Hon. Sir Joſeph Banks, Bart. K. B. and flowers in june. This, as well as the laſt, is a biennial plant [o].]

PROPAGATION AND CULTURE.

1. Common Lavender is propagated by cuttings or ſlips, planted in march in a ſhady ſituation, or in a border where they may be ſhaded by mats until they have taken root, after which they may be expoſed to the ſun, and when they have obtained ſtrength, remove them to the places where they are to remain. Theſe plants will abide much longer in a dry, gravelly or ſtrong ſoil, in which they will endure our ſevereſt winters; but they will grow much faſter in ſummer, on a rich, light, moiſt ſoil, but then they are generally deſtroyed in winter, nor are the plants ſo ſtrong ſcented, or fit for medicinal uſes, as thoſe which grow on a barren rocky ſoil.

It was formerly in uſe to make edgings to borders, but it grows too large for the purpoſe; if often cut in dry weather it is ſubject to decay, and in hard winters ſome of the plants will be killed; it ſhould be planted therefore in beds in the kitchen garden where the ſoil is drieſt.

[On account of its odour however, plants of it ſhould be interſperſed among low ſhrubs and large herbaceous plants in the borders of large gardens and plantations.

All the other ſpecies require the protection of the greenhouſe, except n. 2. which is tolerably hardy; and the laſt, which muſt be preſerved in the dry ſtove. They may all be increaſed by ſlips or cuttings; and alſo by ſeeds, but they do not all produce ſeeds in our climate.]

2. Purple Stoechas, which our old authors call *Sticadove*, *Stiecados*, and *Sticadore*, from the Italian *Stecade*, on account of its being found on the iſlands called Stoechades, may be cultivated by ſowing the ſeeds upon a bed of light dry ſoil in march; when they come up clear them from weeds until they are two inches high, and then remove them. For this prepare a ſpot of light dry ground, lay it level, and tread it out into beds, into which ſet the plants at five or ſix inches diſtance every way; watering and ſhading

[d] L'Heritier. [e] Hort. kew. [f] Linn. diff. [g] Hort. kew. [h] Jacqu. & Linn. diff. [i] Hort. kew. [k] Linn. diff. [l] Gaertner. [m] Hort. kew. [n] Linn. diff. [o] Hort. kew.

them

them until they have taken root. If the winter ſhould prove ſevere, cover them with mats, peas-haulm or other light covering, to guard them againſt the froſt. In march or the beginning of april, the following ſpring, remove them into the places where they are to remain; taking a warm moiſt ſeaſon, if poſſible, for this purpoſe, and not letting them remain long above ground. The ſoil ſhould be a dry warm ſand or gravel, and the poorer the ſoil is, the better will this plant endure the cold of winter. In a rich moiſt ground it will not produce ſo many flowers, nor will they have ſo ſtrong an aromatic ſcent.

It may alſo be increaſed by ſlips or cuttings; but the ſeeds ripen well in this country, and plants raiſed from theſe are much better.

4. Tooth-leaved Lavender, and ſome of the others, ſeldom producing ſeeds in England, are propagated by ſlips or cuttings, planted in april, and treated as directed for the preceding ſorts. Theſe will take root very freely, but muſt be tranſplanted into pots, that they may be ſheltered from ſevere froſt in winter, eſpecially whilſt young. When they have obtained ſtrength, ſome may be planted in a warm ſituation, on a dry ſoil, where being prevented from growing too vigorouſly, they will endure the cold much better than in richer ground.

6. Jagged Lavender, or jagged Stœados, as Gerarde calls it, may be ſown in a border of light earth in the ſpring, and tranſplanted into the borders of the flower garden or into pots. They may be preſerved through the winter in a greenhouſe, but never continuing longer than two years, they are generally raiſed from ſeed every ſeaſon.

The variety from the Canary iſlands is more tender. Sow the ſeeds on a moderate hot-bed in the ſpring. When the plants come up, put each into a ſeparate ſmall pot filled with light earth. Plunge the pots into another hot-bed; and in the beginning of june inure them to the open air, and towards the end of the month place them in a ſheltered ſituation. In july the plants will flower, and if the autumn prove warm, the ſeeds will ripen in ſeptember; but when they do not perfect ſeeds, the plants may be preſerved through the winter in a good greenhouſe, where they will produce flowers and ſeeds moſt part of that ſeaſon.

[LAVANDULA. See *Verbena*.]

LAVATERA. (*So named by Tournefort, from Lavater, a phyſician at Zurich. We have none of his writings.*)

Lin. gen. n. 842. *Reich. n.* 907. *Schreb. n.* 1133. *Tournef. act. gall.* 1706. *t.* 3. *Dill. gen.* 10. *Cavan. diſſ.* 2. 86. *Juſſ.* 272. *Gærtn. t.* 136.

Claſſ. 16. 6. Monadelphia Polyandria.

Nat. order of *Columniferæ—Malvaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* double:

Exterior one-leafed, trifid, obtuſe, ſhort, permanent.

Interior one-leafed, half five-cleft, more acute, more erect, permanent.

COR. *Petals* five, obcordate, flat, ſpreading, affixed below to the tube of the ſtamens.

STAM. *Filaments* numerous, coaleſcing below into a tube; looſe above, (gaping at the tip and ſurface of the tube.) *Anthers* reniform.

PIST. *Germ* orbicular. *Style* cylindric, ſhort. *Stigmas* ſeveral: (ſeven to fourteen) briſtly, length of the ſtyle.

PER. *Capſule* orbicular, compoſed of as many cells as there are ſtigmas, bivalve, and articulated in a whorl round the columnar *receptacle*, at length falling off.

SEEDS ſolitary, reniform.

OBS. Althæa Sp. T. *Fruit comes forth without an umbraculum.*

Lavatera T. *has the fruit covered with an obtuſe umbraculum.*

ESSENTIAL CHARACTER.

Cal. double, outer trifid. *Anth* very many, one-ſeeded.

DESCRIPTIONS, &c.

1. Tree Mallow or Mallow tree riſes with a ſtrong thick ſtalk the height of eight or ten feet (in gardens), dividing into many branches at the top. [In its wild ſtate, when largeſt, from four to ſix feet high, and as much as four inches in diameter. Leaves alternate, numerous, cordate, roundiſh-ſeven-angled (ſome five and others three-angled), the angles blunt, ſoft as velvet, ſhorter than the petioles. Stipules ſhort, ſmooth, acuminate at the tip, broad at the baſe. Flowers moſtly in pairs, ſometimes three together, on upright peduncles an inch and half in length. Outer calyx ovate at the baſe, divided half way into three broad blunt ſegments: inner only half the ſize, divided half way into five ſharp ſegments. Corolla purpliſh red, with dark blotches at the baſe, ſpreading-bell-ſhaped, (like that of the common Mallow) an inch or more in diameter: petals broader at top, narrow at the baſe, ſo that the calyx appears between the claws. Cylinder of filaments purple, woolly at the baſe. Germ very ſmooth. Style uſually eight-cleft at top. Stigmas revolute, reddiſh [a]. The ring or whorl of fruits is ſeven or eight-capſuled: common receptacle awl-ſhaped, with a conoid globule at top, and ſmall creſcent-ſhaped lamellæ at the baſe and the interſtices of the capſules. Capſules reniform-rounded, ſharply three-cornered, membranaceous, wrinkled, cloſed on all ſides, pale-bay-coloured, not opening. Seeds kidney-ſhaped, aſh-coloured [b].

Native of Italy, the Levant and Britain. With us it is ſmaller than it appears in the gardens. Hurſt caſtle. Portland iſland. Denny iſland, near Briſtol. Cornwall and Devonſhire. Teignmouth. Rocks of Caldey iſland. Angleſey, &c. in Wales. Baſſe iſlands, near Edinburgh. Inch-Garvey and Mykrie-Inch, in the Firth of Forth. It flowers from june or july to ſeptember or octobor.

Ray, Moriſon and others diſtinguiſh ours from the Italian plant; the leaves of ours being ſmaller, more hoary on the upper ſurface, and the upper ones more angular; the flowers not ſo large, and of a paler red colour. Moriſon found it growing plentifully on the iſland of Pierre Percé on the coaſt of Bretagne.

2. Leaves ſoft, waving on the edge, with brimſtone-coloured mice ſhining in the ſun on the upper ſurface. Stems from two to three feet in height.

Native of Spain [c] and Portugal.

3. Stem round, branched, five feet high, villoſe at top, reddiſh. Leaves ſoft, whitiſh, tomentoſe, unequally ſerrate; the lower ſubcordate-haſtate, five-angled; the upper ovate, three-cuſped, the middle lobe narrowed, acute, oblong. Stipules ovate-lanceolate, villoſe. Flowers on ſhort peduncles, axillary, ſolitary, very ſeldom two together; terminating ones in a ſpike. Outer calyx ovate, with roundiſh-acute ſegments: inner larger, with lanceolate, acute ſegments. Corolla large, ſpreading very much, reddiſh-purple: petals with narrowed claws, covered with white hairs, inſerted into a fleſh-coloured tube. Stamens purple. Germ roundiſh-compreſſed, with twenty grooves. Style divided into about twenty parts. Stigmas long, recurved. Capſules about twenty, black, ſmooth, fixed in a ring about a thick ſtriated cone. When the ſeeds are ripe, that part which is next to the axis appears naked, on account of the pellicle which forms the internal part of the capſule adhering to the axis [d].

Linnæus obſerves, that the leaves of the firſt year are very large, and thoſe of the following years much ſmaller, which is a circumſtance common to this with other plants of the ſame natural order. It bears a great reſemblance to the next ſpecies, but in this the flowers are ſolitary, on a very ſhort peduncle; and the outer calyx is acuminate, almoſt three-parted, the length of the inner.

Native of the South of France. It flowers from june to octobor. Cultivated by Mr. Hugh Morgan in 1570, according to Lobel [e].

4. Stem round, branched, from three to four feet in height. Leaves alternate, petioled, ſhorter than the petioles, roundiſh but with the border ſo rolled back as to appear triangular. Stipules cordate, broad, acuminate, ſerrate. Flowers axillary: three peduncles moſtly one-flowered in each axil, upright, ſhorter than the petiole. Segments of the outer calyx broad-cordate, acuminate. Inner calyx twice as large, five-cornered-acuminate, with the corners prominent. Corolla large, ſpreading, pale purple, with the claws white, hairy. Capſules about fifteen, in a ring about a column ending in a point [f].

Linnæus obſerves, that the whole plant is tomentoſe, being covered with very ſmall glutinous hairs, with other larger ones ſtellate at top mixed among them.

Native of France and Spain. It flowers from june to ſeptember. Cultivated by Mr. Miller, in 1759 [g].

5. Native of Portugal. Cultivated by Mr. Miller in 1748. It flowers in auguſt and ſeptember [h].

6. Stem reddiſh, covered with bundles of hairs ſo ſmall as to ſeem dots of meal, branched, two feet high and more. Leaves on the older plants ſmall, ſomewhat plaited, five-nerved; on the younger plants and branches double the ſize (near two inches in diameter). Stipules awl-ſhaped, ſmall, tomentoſe. Flowers axillary, ſeldom two together, on declining peduncles, ſhorter than the petiole. Segments of the outer calyx ovate-acute; of the inner twice as large, lanceolate. Corolla large, twice the ſize of the common Mallow, and more, ſpreading very much, whitiſh, with very narrow purple claws. Tube of the filaments dark purple. Germ orbicular-compreſſed: ſtyle multifid: ſtigmas oblong revoluſe. Fruit within the calyx, conſiſting of twelve kidney-ſhaped capſules, placed in a ring round a column, terminated by a ſhort acuminate cone.

Native of Spain and the South of France. It flowers from july to ſeptember [i].

Cavanilles has another ſpecies (diſſ. 282. t. 139. f. 1.) which he names *L. africana*, being a native of the northern part of Africa, as well as Spain. He ſays it is allied to L. maritima. The ſtem is ſhrubby, as in that, branched, covered with a ſhort down, compoſed of a web of hairs in bundles, and four feet in height. Leaves alternate, almoſt equal to the petioles, five-lobed, crenate, ſoft, hoary. Stipules narrow, upright. Flowers axillary, (not ſolitary) but in pairs, drooping on peduncles an inch in length. Outer calyx deeper cut than in the other ſpecies into three ovate blunt ſegments: inner cut half way into five ſharp ſegments: both tomentoſe. Corolla almoſt white, the petals being of an extremely pale purple, rounded-emarginate, large, ſpreading. Cylinder of filaments deep purple, naked at the baſe. Germ orbicular-compreſſed, twelve-grooved, very ſmooth: ſtyle white: ſtigmas twelve, long, reflex, purple. Fruit within the calyx, compoſed of twelve kidney-form capſules, roughened at the back. Miller has a ſpecies under the name of *L. africana*, which is an annual, and very different from this.]

7. Stem five or ſix feet high, woolly, [branched. Lower leaves heart-ſhaped, crenate, roundiſh-lobed: upper haſtate, on ſhort petioles. Stipules lanceolate. Flowers axillary, ſolitary, peduncled; peduncles longer than the leaf. Calyxes ſubtomentoſe: ſegments of the outer heart-ſhaped, with a very ſharp point; of the inner oblong, acute. Corolla large, ſpreading, pale violet or purpliſh] ſhaped like thoſe of the Marſh-mallow, but larger; [petals emarginate [k]. Capſules about twenty (fourteen Cavanilles) in a wing, of a papery ſubſtance, ſomewhat rugged, about a columnar receptacle, which has many wings from the permanent ſides of the capſules, like the cogs of a mill-wheel, ending in a conical-awl-ſhaped point. Seeds flatted a little, ſmooth, ſubcinereous or brown [l].

Native of Sweden, Germany, Hungary, Tartary,

[a] Cavanilles, Withering. [b] Gærtner. [c] Moriſon. [d] Cavanilles. [e] Cavanilles. [f] Cavanilles. [g] Hort. kew. [h] Ibid. [i] Cavanilles. [k] Ibid. [l] Gærtner.

in hedges. Cultivated in 1732, by James Sherard, M.D. It flowers from july to ſeptember [m].

8. Root annual, fibrous, of thick fibres a foot in length, with innumerable other capillary fibres. Stem round, rugged, five feet high, branched. Leaves on long petioles, very ſoft, tomentoſe, toothed, ſeven-angled, the angles of the upper ones ſharper. Stipules lanceolate, ciliate, bowing at bottom and then ereƈt. Flowers axillary, about four together, on upright pedunƈles. Outer calyx cup-ſhaped, with ovate ſegments: inner a little longer, five-cornered above, with lanceolate ſegments. Corolla twice the length of the calyx, pale blue, with oblong, emarginate petals. Germ orbicular-flatted, ten-grooved. Stigmas ten. Fruit ſmooth, within the calyx. Capſules ten, round a column terminated by a hemiſphere with a very ſmall point at top, diſappearing when the fruit is ripe, and leaving a hole in the middle of the capſules, which then turn black [n].

Native of the iſland of Candia or Crete. Cultivated in 1768, by Mr. Miller. It flowers in july [o].

9. Root annual, white, with ſpreading beards. Stem round, two feet high, branched, the lower branches almoſt horizontal. Leaves crenate-toothed, ſmooth, on long petioles, gradually narrowed towards the tip. Stipules ovate-lanceolate, ciliate, bowed at bottom and then ſtraight. Flowers ſolitary, axillary, on pedunƈles ſhorter than the petiole. Outer calyx ſemitrifid, with keeled ſegments: inner larger, with lanceolate ſegments, curled at the edge. Corolla large, ſpreading bell-ſhaped, pale fleſh-colour with whitiſh lines; petals broader above, crenate, frequently rolled up, the edges of the claws deep purple. Germ very ſmooth. Style multifid. Stigmas pale-fleſh-coloured, longer than the tube, thirteen to eighteen. Fruit hemiſpherical, convex beneath, covered at top with a circular, concave, ſmooth, lid [p], or peltate umbrella. There are about twenty capſules in a whorl; they are brown, cloſed all round and not opening, with a longitudinal raiſed line along the back, elegantly marked on the ſides with flexuoſe ſtreaks drawn from the circumference to the centre. Seeds ferruginous [q].

Native of the South of Europe and the Levant. Cultivated in 1640, according to Parkinſon. It flowers from july to ſeptember [r].

This ſpecies varies much, and the varieties are conſtant [s]. Hence Mr. Miller makes three ſpecies out of it,] 1. L. althææfolia, a native of Syria, with an upright branching ſtalk, two feet high; the under leaves cordate-orbiculate, ſmooth, on long foot-ſtalks; the upper divided into three acute lobes: the flowers on long pedunƈles from the axils, very large, and ſpreading open, like thoſe of the Marſh-mallow, of a pale red or roſe-colour. There is a variety of it with white flowers.—2. L. africana, t. 161. f. 2. of his figures: native of the Cape of Good Hope, whence the ſeeds were brought to Holland. This differs from the preceding in the ſhape of the leaves; the lower having angles, and the upper being arrow-pointed; the ſtalks are hairy, the flowers larger, and of a brighter red colour.—3. L. trimeſtris is a native of Spain and Sicily. It riſes with ſlender ſtalks about two feet high, covered with a brown bark. The lower leaves are roundiſh, and the upper are angular, ſome of them arrow-pointed. The flowers are not half ſo large as either of the former, and are of a pale red colour; they ſtand on ſhort pedunƈles.

They are all annual herbaceous plants, flowering in july; and the ſeeds ripen in autumn.

PROPAGATION AND CULTURE.

All the ſhrubby ſorts are eaſily propagated by ſeeds, which ſhould be ſown in the ſpring upon a bed of light earth; and when the plants are about three or four inches high, they ſhould be tranſplanted to the places where they are deſigned to remain; for as they ſhoot out long fleſhy roots which have but few fibres, they do not ſucceed well if they are tranſplanted after they are grown large. If the ſeeds of theſe plants are permitted to ſcatter on the ground, the plants will come up the following ſpring; and when they happen to fall into dry rubbiſh, and are permitted to grow therein, they will be ſhort, ſtrong, woody, and produce a greater number of thoſe flowers than plants which are more luxuriant. As theſe plants continue a long time in flower, a few plants of each ſort may be allowed a place in all gardens where there is room.

Several of theſe ſhrubby ſorts will laſt only two years with us, unleſs on dry ground, where they will endure three or four years, but ſeldom longer.

Moſt of them require the proteƈtion of the green-houſe, or at leaſt to have the ground about them covered with old tanner's bark to keep out the froſt in ſevere winters.

The annual ſorts are propagated by ſeeds: the ſeaſon for ſowing them is the end of march or the beginning of april, upon a bed of freſh light earth; and when the plants are come up, careſully clear them from weeds; and in very dry weather, now and then refreſh them with water. When they are about two inches high, tranſplant them into the places where they are deſigned to remain, which ſhould be in the middle of the borders in the flower-garden; for if the ſoil is good, they will grow two or three feet high; in tranſplanting them, take them up very careſully, preſerving a ball of earth to their roots, otherwiſe they are apt to miſcarry; and alſo water and ſhade them until they have taken root, after which they will require no other care but to clear them from weeds, and to faſten them to ſtakes, to prevent their being injured by ſtrong winds. You may alſo ſow their ſeeds in autumn, and when the plants are come up, tranſplant them into ſmall pots, which, towards the end of october, ſhould be placed in a common hot-bed frame, where the plants being defended from ſevere froſts, will abide the winter very well; and in the ſpring, ſhake them out of the pots, and plant them into larger, or elſe into the full ground, where they may remain to flower. The plants thus managed will be larger, and flower ſtronger and earlier than thoſe ſown in the ſpring, and from theſe you will conſtantly have good ſeeds, whereas thoſe ſown in the ſpring ſometimes miſcarry.

LAVENIA. (*This name was taken up by Linneus as a trivial from Sherard in Ray's ſupplement, and as a genus by Solander. It is perhaps vernacular.*)

Lin. gen. Schreb. n. 1268. *Swartz prodr.* 112.

Adenoſtemma. *Forſt. gen.* 45.

Claſs. 19. 1. Syngeneſia Polygamia Æqualis.

Nat. order of *Compoſitæ Diſcoideæ*.

GENERIC CHARACTER.

CAL. *Common* ovate, ſubimbricate; *ſcales* ten to fourteen, lanceolate, equal, permanent.

COR. *Compound* uniform: *corollets* hermaphrodite equal, (fifteen to twenty).

Proper funnel-form, dilated at the baſe; *border* five-cleft, patulous.

STAM. *Filaments* five, filiform, ſhorter than the tube. *Anthers* oblong, flattiſh twin, ſlightly connate.

PIST. *Germ* oblong. *Style* filiform, longer than the corollet, two-parted. *Stigmas* flattiſh, clubbed.

PER. none. *Calyx* permanent, ſpreading.

SEEDS ſubclavate, a little wrinkled, viſcid with glandules; *down* with three awl-ſhaped awns, glanduloſe at the baſe.

REC. naked.

ESSENTIAL CHARACTER.

Cal. nearly regular. *Style* bifid. *Down* three-awned, glandular at the tip. *Recept.* naked.

SPECIES.

1. Lavenia decumbens.

Chrysanthemum aquaticum, schrophulariæ folio, Lavenia dictum. *Raii suppl.* 217.
Stem branched erect, leaves elliptic sharply serrate.

DESCRIPTIONS, *&c.*

1. Stem herbaceous. Leaves opposite, petioled, cordate sometimes but seldom ovate, blunt, bluntly serrate, petioled. Peduncles terminating, long, usually bifid and two-flowered. Calyx many-leaved, simple, ovate. Pistil longer than the corollet. Seeds terminated by two coloured bristles. It has the appearance of a Verbesina*.
Annual and native of Jamaica.
2. Root annual, fibrous, whitish. Stems pale green or whitish, slender, hairy. Leaves set with whitish hairs. Heads of flowers flat, consisting of numerous pale-blue florets. Style also pale blue, with a dark blue stigma white at top. Calyx hairy*.
Native of the East Indies and the Society isles. Forster named it Adenostemma, from ἀδὴν a gland, and στέμμα a crown or garland, the seed, instead of a down, being crowned with three glands.
The figure in hort. malab. does not very well agree with Forster's drawing, but the specimens in the Banksian herbarium vary as much to the full.

LAUGERIA. (*Named* Laugieria *by Jacquin from Robert Laugier, Professor of Chemistry and Botany at Vienna. Petrus Laugerius was a physician at Sedan: and described and figured above* 1400 *rare plants of that neighbourhood, never published.* P. M. Slegelii Programma, Jenæ 1639. qu.)
Lin. gen. n. 259. *Reich. n.* 280. *Schreb. n.* 354. *Jacqu. amer.* 64. *Juss.* 206.
Class. 5. 1. Pentandria Monogynia.
Nat. order of *Rubiaceæ*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, tubular, superior, with unequal mouth, small, deciduous.
COR. one-petalled, salver-form. *Tube* very long. *Border* five-cleft; *divisions* obovate.
STAM. *Filaments* five, very short. *Anthers* linear, long, beneath the throat.
PIST. *Germ* subovate, inferior. *Style* filiform, rather longer than the tube. *Stigma* headed.
PER. *Drupe* roundish, umbilicated with a point.
SEED. *Nut* two or five-celled, *Sw.* furrowed, *Jacqu.*

ESSENTIAL CHARACTER.

Cor. five-cleft. *Drupe* with a five-celled nut.

SPECIES.

1. Laugeria odorata.
Lin. spec. 276. *syst.* 231. *Reich.* 1. 535. *Swartz prodr.* 49. *Jacqu. amer.* 64. *t.* 177. *f.* 21. *pict.* 36. *t.* 259. *f.* 16.
Edechia. *Loefl. it.* 306, 271, 259.
Leaves subovate acute smooth, stem somewhat spiny, racemes panicled, drupes with five-celled nuts.
2. Laugeria lucida.
Swartz prodr. 48. *Vahl symb.* 3. 40. *t.* 57. *Loefl. it.* 270. *n.* 154.
Leaves oblong blunt entire membranaceous shining, racemes dichotomous, drupes with two-celled nuts.
3. Laugeria tomentosa.
Swartz prodr. 48.
Leaves ovate acute entire tomentose underneath, racemes dichotomous, drupes with a two-celled nut.

DESCRIPTIONS, *&c.*

1. This is an upright branching shrub ten feet high. Leaves quite entire, petioled, opposite, two inches long. Racemes loose, axillary, the length of the leaves. Flowers of a dirty red, very sweet during the night, peduncled, with one sessile in each division of the raceme. Fruits black, larger than peas, soft, very numerous, falling when ripe with every slight motion of the bush. It comes up both unarmed and with long, opposite, straight spines from the seed of the same shrub.
Native of America, Carthagena, Havanna, &c.
2. Branches round, smooth, covered with an ash-coloured bark, scarred at top with the fallen leaves. Leaves in clusters at the ends of the branchlets, petioled, opposite, two or three inches long, very smooth and even, nerved, quite entire. Racemes from the axils of the terminating leaves, solitary, opposite, the length of the leaves, bifid, reflex at the tip, almost as in Tournefortia. Flowers on short pedicels, distant, all directed the same way, on the inner side of the peduncles. Calyxes small, smooth, five-cleft. Corolla smooth*.
Native of the West Indies, Jamaica, and Santa Cruz.
3. Native of Jamaica*.

Class. 9. 1. Enneandria Monogynia.
Nat. order of *Holoraceæ. Lauri*, Juss.

GENERIC CHARACTER.

CAL. none (unless you call the corolla so.)
COR. *Petals* six, ovate, acuminate, concave, erect; the *alternate* ones exterior.
Nectary consisting of three acuminated coloured tubercles, ending in two bristles, standing round the germ.
STAM. *Filaments* nine, shorter than the corolla, compressed, obtuse, three in each rank. *Anthers* growing on each side to the margin of the filament on the upper part.
Glandules two, globose, with a very short footstalk, affixed to each filament of the inner rank near the base.
PIST. *Germ* subovate. *Style* simple, equal, length of the stamens. *Stigma* obtuse, oblique.
PER. *Drupe* (or berry) oval, acuminate, one-celled, comprehended by the corolla.
SEED. *Nut* ovate-acuminate. *Kernel* of the same form.
OBS. *The greater part of the species, including the Cinnamon, and Camphor, are hermaphrodite: but in some there are male flowers apart in dioecia, as in* L. nobilis, *where there are also frequently from eight to fourteen stamens, with naked four-parted corollas.*
The corpuscles annexed to some of the stamens afford the essential character.
The stamens vary as to number. R.

ESSENTIAL CHARACTER.

Cal. none. *Cor.* calycine, six-parted. *Nect.* of three two-bristled glands, surrounding the germ. *Filam.* inner glanduliferous. *Drupe* one-seeded.

Leaves nerveleſs oblong hairy, racemes wide terminating.

DESCRIPTIONS, *&c.*

This genus conſiſts of trees or ſhrubs. Leaves moſtly entire, in a few nearly oppoſite, commonly perennial, as in moſt trees of the torrid zone. Flowers in the greater part in a ſort of panicle either axillary or terminating, in a few ſolitary or glomerate from the axils, ſometimes dioecous. Calyx of ſome deciduous, of the reſt permanent, entire or lobed. Fruit a drupe, in moſt like that of the Olive or Cherry; in L. Perſea pear-ſhaped and large [a]. It contains many important ſpecies beſides the Sweet Bay, as Cinnamon, Caſſia, Camphor, Saſſafras, &c.

1. Jacquin deſcribes the Cinnamon tree of America as twenty feet high or more, the trunk about ſix feet high, a foot and half in diameter, the outer bark ſmoothiſh and of a duſky cinereous colour; it has ſpreading branches that form an elegant head. Leaves oppoſite or nearly ſo, ovate-oblong, oblong-acuminate, or ſubovate, bluntly acuminate, quite entire, ſhining, coriaceous, on ſhort petioles, from three to five inches long; the three nerves ſpring from the petiole, and either immediately recede from each other, or continue united for a line or two and then diverge; they are of a bright green on the upper ſurface, but pale on the under, with the nerves whitiſh. On the younger branches or twigs ariſe ſlender common peduncles, from oppoſite axils, the terminating ones an inch, the others two or three inches long, three-flowered at top, or elſe trifid, with each diviſion three-flowered. Flowers ſmall, greeniſh yellow, almoſt inſipid, with a ſomewhat fetid ſmell, reſembling that of Lilium Martagon. Fruit the form and ſize of a middling Olive, inſipid, deep blue and ſoft, incloſing a thin, pale-coloured nut with a white kernel, which germinates ſoon after it falls, and therefore cannot eaſily be tranſported to a diſtance. The inner bark perfectly reſembled the Oriental Cinnamon in ſmell, taſte and figure; the only difference is that it has a coarſer texture, and a more acrid taſte, which may ariſe from the climate. But the varieties of Cinnamon are numerous. The timber is white and not very ſolid. The root is thick and branching, and exudes abundance of Camphor.

Native of Martinico, on the mountain Calebaſſe; flowering in February and march [a]. It is a native alſo of Braſil.

In the Flora zeylanica of Linneus the fructification only is deſcribed. The perianth is ſaid to be ſix-parted, with ovate-oblong ſegments. Stamens fix, one faſtened to each ſegment of the calyx; with an anther on each ſide at the tip. Beſides theſe, three other ſtamens terminated by an anther, and having a gland on each ſide above the baſe; finally three other ſharp ſtamens, bearing an anther that is ſcarcely fertile.—Jacquin and Loureiro mention only nine ſtamens.

Loureiro deſcribes the wild Cinnamon of Cochinchina as a middle-ſized tree. Leaves oblong, three inches in length, ſharpiſh at both ends, quite entire, flat, the three nerves diſappearing towards the tip, ſomewhat veined, ſmooth, pale green, petioled, ſcattered. Peduncles many-flowered, long, lateral and terminating. Flowers hermaphrodite, white. Corolla ſix-parted. The three inner ſtamens of the nine biglandular. Fruit a ſmall, ovate, blackiſh, ſhining oily Berry, containing one ſeed of the ſame ſhape.

Gærtner deſcribes the fruit of the Ceyloneſe Cinnamon as a ſubglobular berry, flatted a little at top and toruloſe, covered at the baſe by the calyx, which is thick, coriaceous, angular, ſublobate, and having from ſix to nine unequal teeth: the pulp or fleſh is very thick, and grows fungoſe with age, ſmelling ſtrong of Cinnamon. Seed ſpherical, covered with a cruſtaceous, brittle, thin coat.

The following account of the Cinnamon of Ceylon is given by Albertus Seba, from the chief inſpector of the Cinnamon trade in that iſland, and is printed in Act. nat. cur. and the Philoſophical Tranſactions.

The beſt ſort of Cinnamon, which grows in great plenty in Ceylon, and is peculiar to that iſland, is called by the natives *Raſſe Coronde*, or ſharp ſweet Cinnamon. It is this choice ſort which is exported by the Dutch Eaſt India Company, and it is prohibited, under ſevere penalties, to mix any other ſort with this.

The ſecond is called *Canatte Coronde*, or bitter aſtringent Cinnamon. The bark of this comes off very eaſily, and ſmells very agreeably when freſh, but has a bitter taſte. It has an advantage that it is not ſo plentiful as the firſt; becauſe it requires much ſkill and attention to diſtinguiſh them. The root of this yields a very good ſort of Camphor.

The third is called *Copperee Coronde* or camphorated Cinnamon, becauſe it has a very ſtrong ſmell and taſte of Camphor. It grows plentifully in the iſland, but not in the eaſtern part. However they find means to ſend it over privately, and ſell it to the Danes and Engliſh, trading upon the coaſts of Coromandel. Beſides there is a ſort of Canella growing upon the continent of India about Goa, which is very like this, though it has nothing of the true Cinnamon. This agrees in many things with Canella malabarica ſylveſtris, a wild Cinnamon tree, growing upon the coaſts of Malabar. And although with regard to the ſhape of the tree, and the outward appearance of the bark and leaves, very little difference is to be obſerved between theſe Canellas and the firſt Cinnamon, yet that is vaſtly ſuperior in richneſs, quality and ſweetneſs.

The fourth ſort is called *White Coronde*, or Sandy Cinnamon, becauſe upon being chewed it feels gritty, or as if grains of ſand were between the teeth. The bark comes off eaſily, but is not ſo readily rolled up. It is of a ſharp bitteriſh taſte, and the roots yield only a ſmall quantity of Camphor.

[a] Juſſieu.

[a] Jacquin.

The fifth ſort is called *Sewel Coronde*, glutinous or mucilaginous Cinnamon. This acquires in drying a conſiderable degree of hardneſs: it has little taſte, and an ungrateful ſmell; but the colour is very fine, and the natives mix a good deal of it with the beſt ſort, the colour being much alike, except that in the genuine ſort there are ſome few yelloviſh ſpots towards the extremities.

The ſixth ſort is called *Nieke Coronde*, the tree bearing much reſemblance to another tree which the natives call *Nieke Gas*. The bark has no taſte or ſmell, and is only uſed by the natives in medicine. By roaſting it they obtain an oil, with which they anoint themſelves, to keep off infection: and they expreſs a juice from the leaves, with which they rub their heads, to cool and ſtrengthen the brain.

The ſeventh is called *Dawel Coronde* or Drum Cinnamon: the wood being light and tough, and uſed by the natives for making drums. The bark is taken off whilſt the tree is yet growing; is of a pale colour, and is uſed for the ſame purpoſes as the ſixth.

The eighth ſort is called *Cutle Coronde*, thorny or prickly Cinnamon; the tree being very prickly. The bark is in ſome meaſure like that of the true Cinnamon, but it has nothing of the taſte or ſmell, and the leaves differ very much. The natives apply the root, bark and leaves in form of cataplaſms to tumours.

The ninth ſort is called *Mael Coronde* or flowering Cinnamon, being always in bloſſom. The flowers come neareſt to thoſe of the firſt ſort, but they bear no fruit. The wood never becomes ſo ſolid and weighty in this as in the others, which are ſometimes eight, nine or ten feet in circumference. If this tree be cut or bored into, a limpid water will iſſue from the wound, as from the Birch tree, but it is of no uſe, any more than the leaves and bark.

There is a tenth ſort called *Teupat Coronde* or three-leaved Cinnamon, which does not grow near the Dutch ſettlements, but higher up towards Candia.

Some of theſe are probably the Caſſia, and the ninth is the male tree of the true Cinnamon.

With reſpect to the time when the bark is fit to be taken off, ſome trees are ready two or three years ſooner than others, owing to the difference of ſoil which they grow in: thoſe for inſtance which grow in vallies where the ground is a fine whitiſh ſand will be fit to have the bark taken off in five years; but others which ſtand in a wet ſlimy ſoil, muſt have ſeven or eight years to grow before they are fit to bark. Thoſe trees are alſo later which grow in the ſhade of other large trees, whereby the ſun is kept from their roots. Hence alſo it is, that the bark of ſuch trees has not that ſweetneſs obſervable in the bark of thoſe which grow in a white ſandy ground, where with little wet they ſtand full expoſed to the ſun; but is rather of a bitteriſh taſte, ſomewhat aſtringent, and ſmells like Camphor.

For by the heat of the ſun's rays the Camphor is made ſo volatile, that it riſes up and mixes with the juices of the tree, where it undergoes a ſmall fermentation, and then riſing ſtill higher between the wood, and the thin inner membrane of the bark, it is ſo effectually diffuſed through the branches and leaves, that there is not the leaſt footſtep of it to be perceived. Mean while that thin and glutinous membrane which lines the bark on the inſide attracts all the pureſt and ſweeteſt particles of the ſap, leaving the thick and groſs ones to puſh forwards, in order to nouriſh the branches, leaves and fruit.

If the bark be freſh taken off, that ſap which remains in the tree has a bitteriſh taſte, not unlike that of Cloves. On the contrary, the inner membrane of the bark, when freſh taken off, has a moſt exquiſite ſweetneſs, whilſt the outer part differs very little in taſte from that of other trees. But when the bark is laid in the ſun to be dried and roll up, this oily and agreeable ſweetneſs of the inner membrane is diffuſed through the whole.

The bark may be taken off from trees that have ſtood fourteen, fifteen or ſixteen years, according to the quality of the ſoil: but beyond that time they loſe by degrees their agreeable ſweetneſs, and the bark has more of the taſte of Camphor. Beſides, the bark is then become ſo thick, that when laid in the ſun, it will no longer roll up, but remain flat.

To account for the great quantities of Cinnamon trees ſtill remaining on the iſland of Ceylon, after the general exportation of the bark that has prevailed during ſeveral centuries, ſome authors have aſſured us that after the bark has been ſtripped off the tree, it becomes fit to be ſtripped a ſecond time in four or five years. But this aſſertion is no leſs contrary to obſervation than it is to the common courſe of nature. The truth is, the barked trees being cut down, quickly put forth new ſhoots, which in a period of from five to eight years come again to the knife. Great numbers alſo of trees are continually ſpringing from the fruit which either drops upon the ground, or is diſſeminated by the wild doves called there Cinnamon-eaters: inſomuch that here and there along the roads ſuch quantities of theſe young trees are to be ſeen, as to look like little woods.

The inner bark of this ſpecies in the ſpice ſo well known under the name of Cinnamon. The uſe of the Cinnamon-tree however is not confined to the bark, for it is remarkable that the leaves, fruit, and root, all yield oils of different qualities, and of conſiderable valtie. That produced from the leaves is called Oil of Cloves, and Oleum Malabathri: that from the fruit is extremely fragrant, and of a thick conſiſtence, and at Ceylon is ſaid to be made into candles, for the ſole uſe of the king; and the bark from the root not only affords an aromatic oil, which has been called Oil of Camphor, but alſo a ſpecies of Camphor, which is purer and whiter than the common Camphor. The bark of the Cinnamon-tree, while on the tree, is firſt ſtripped of its outer greeniſh coat; and is then cut longitudinally from the tree, and dried in the ſand, till it becomes fit for the market, when it is of a reddiſh yellow or pale ruſty iron-colour, very light, thin, and curling up into quills or flakes. Cinnamon is one of the moſt grateful of aromatics; its qualities are extracted both by water and ſpirit. It is an aſtringent, and corroborates the viſcera, and proves of great ſervice in ſeveral kinds of alvine fluxes, and immoderate uterine diſcharges. An eſſential oil is ſometimes prepared from Cinnamon, which is moſt exceſſively pungent, ſo as to produce an eſchar on the ſkin, if applied to it: but in doſes of a drop or two properly diluted, with ſugar, mucilages, &c. it is ſaid to be one of the moſt immediate cordials and reſtoratives in caſes of lanquor and debility.

Cinnamon is native of the iſland of Ceylon. Linneus in his Hortus Cliffortianus (1737), ſpeaks of it as a forbidden tree not then known in Europe but from dried ſpecimens, and not eaſy to be introduced, probably from the jealouſy of the Dutch; it was however cultivated by Mr. Miller before 1768: and is now cultivated both in our territories in the Eaſt Indies, and in the iſlands of the Weſt Indies. Monſ. Poivre alſo introduced it, along with the Nutmeg and Clove, into the iſles of France and Bourbon.

Dr. George Young had one hundred and forty Cinnamon trees at St. Vincent's in may 1772. In 1789 it was ſucceſsfully cultivated in Jamaica, from trees taken in a French prize by Admiral Rodney, and preſented by him to the aſſembly of that iſland. In 1792, ſamples of this Cinnamon, ſent by Dr. Dancer, were examined by a committee of the Society of Arts, &c. and ſome eminent dealers in that ſpice; who were of opinion that two of the ſamples were excellent, and even preferable to any Cinnamon imported from Ceylon, both in colour and flavour.

Mrs. Anſley brought two Cinnamon trees from Ceylon to Madras: and Dr. Roxburgh procured ſix trees in 1789[c].

2. Caſſia or Wild Cinnamon, though diſtinguiſhed by Linneus and others, is thought by the beſt judges not to be a diſtinct ſpecies from the preceding or true Cinnamon. Linneus's diſtinction founded upon the leaves is certainly nugatory, and the difference of the

[c] Long's Jamaica, 913. Trans. Soc. Arts. vol. 10, 11.

bark may be owing to ſoil or ſituation, but more probably to want of ſkill or attention in the cultivators. The Caſſia bark is coarſer, and will not roll up like true Cinnamon, but the eſſential difference between the bark of Cinnamon and Caſſia is that the former is always dry, whereas the latter becomes mucilaginous in chewing; hence it has been ſuggeſted to me as a conjecture on the moſt reſpectable authority that the ſuperior excellence of Cinnamon bark may be in great meaſure owing to its having been deprived of that mucilage which adheres to its interior ſurface. At leaſt we are certain that in a curious drawing of Herman's, now in the poſſeſſion of Sir Joſeph Banks, repreſenting the proceſs of cutting and preparing Cinnamon in the iſland of Ceylon, one of the principal figures is that of a woman who is evidently employed in this operation of ſcraping the mucilage from the inner ſurface of the bark.

The Caſſia is deſcribed at great length in the Hortus Malabaricus, and Linnæus refers to this as an excellent deſcription of the true Cinnamon.

Mr. Marſden informs us that the Caſſia trees grow from fifty to ſixty feet high, with large ſpreading horizontal branches, almoſt as low as the earth. The leaves are about four inches long, narrower than thoſe of the Bay, and more pointed, deep green, with a ſmooth ſurface and plain edge: the principal fibres or nerves take their riſe from the peduncle. The young leaves are moſtly of a reddiſh hue. The bloſſoms grow ſix in number upon ſlender footſtalks, cloſe to the bottom of the leaf. They are monopetalous, ſmall, white, and ſtellated in ſix points. The ſtamina are ſix (Linnæus ſays nine), with one ſtyle growing from the germ, which ſtands up in three browniſh ſegments reſembling a cup. The fruit of Cinnamon and Caſſia are very different according to Gærtner's figure and deſcription. The root is ſaid to contain much camphire. The bark is commonly taken from ſuch of the trees as are a foot or eighteen inches diameter, for when they are younger, it is ſaid to be ſo thin, as to loſe all its qualities very ſoon. Thoſe trees which grow in a high rocky ſoil have red ſhoots, and the bark is ſuperior to that which is produced in a moiſt clay, where the ſhoots are green. I have been aſſured, ſays Mr. Marſden, by a perſon of extenſive knowledge, that the Caſſia produced on Sumatra is from the ſame tree that yields the true Cinnamon, and that the apparent difference ariſes from the leſs judicious manner of quilling it. Perhaps the younger and more tender branches, ſhould be preferred; perhaps the age of the tree, or the ſeaſon of the year ought to be more nicely attended to; and it is ſuggeſted that the mucilage which adheres to the inſide of the freſh-peeled rind, does, when not carefully wiped off, injure the flavour of the Caſſia, and renders it inferior to that of the Cinnamon. It is ſaid to be ſometimes purchaſed by the Dutch merchants, and ſhipped for Spain as Cinnamon, being packed in boxes which came from Ceylon with that article [a]. It is of the ſame quality with Cinnamon, but inferior in fragrancy and efficacy. The leaves are called by officinal writers *folia Malabathri*, and the bark *Caſſia lignea*.

It is a native of Malabar, Java, Sumatra, chiefly in the northern and central part of the iſland, in thoſe diſtricts which lie inland of Tappanooly.]

3. The Camphire-tree is very near a-kin to the Cinnamon-tree, from which it differs in the leaves, thoſe of the latter having three ribs running longitudinally from the foot-ſtalk to the point, where they ſoon diminiſh; whereas in this the ribs are ſmall and extend towards the ſides; their ſurface is ſmooth and ſhining. They are male and hermaphrodite in different trees.

[It is a large tree with aſcending branches. Leaves quite entire, ſmooth, moſtly alternate, but ſome oppoſite, petioled, whitiſh underneath. Flowers white, on ſimple, long, lateral peduncles. Berry ſmall, ovate, duſky or browniſh red [b].

Mr. Marſden alſo deſcribes it as equal in height and bulk to the largeſt timber trees, being frequently found upwards of fifteen feet in circumference. The leaf is ſmall, of a roundiſh oval, ending in a long point or tail, the fibres running all parallel and nearly ſtraight. The wood is in much eſteem for carpenter's purpoſes, being eaſy to work, light, durable, and not liable to be injured by inſects, particularly the *coombang*, a ſpecies of bee, which from its faculty of boring timber for its neſt, is called the *Carpenter*.

Native of China, Japan, Borneo and Sumatra, if the Capoor Barroos of the Malays be the product of the ſame tree. It was cultivated in 1731, by Mr. Miller [c].

The chief part of the Camphor that is uſed in Europe is prepared from this tree in Japan. The Japaneſe ſplit the wood into ſmall pieces, and ſublime or diſtil it with water in an iron retort, covered with an earthen or wooden head, in the hollow of which they ſaſten hay or ſtraw, to which the Camphor, as it riſes, adheres. This Camphor is browniſh or white, but in very ſmall ſemipellucid grains. It is packed up in wooden caſks, and thus ſent to India and Europe, where it is purified by a ſecond ſublimation, and reduced into the ſolid maſs in which we find it in our ſhops.

Native Camphor, the *Capoor Barroos* of the Malays, is a production for which Sumatra and Borneo, have in all ages been much celebrated; the Arabians being, at a very early period, acquainted with its virtues. Camphor being of a dry nature does not exude from the tree, or manifeſt any appearance on the outſide. The natives, from long experience, know whether any is contained within, by ſtriking the tree with a ſtick. In that caſe, they cut it down and ſplit it with wedges into ſmall pieces, finding the Camphor in the interſtices in the ſtate of a concrete cryſtallization. Some have aſſerted that it is from the old trees alone that this ſubſtance is procured, and that in the young trees it is in a fluid ſtate, called *mucilo capoor* or camphor oil; but this is a miſtake. The ſame ſort of tree that produces the fluid, does not produce the dry, tranſparent flaky ſubſtance, nor ever would. They are readily diſtinguiſhed by the natives. Many of the trees however produce neither the one nor the other.

The native Camphor is purchaſed on the ſpot at the rate of ſix Spaniſh dollars the pound, or eight dollars the catty for the beſt ſort; which ſells at the China market for about twelve or fifteen hundred dollars the pecul of one hundred catties, or one hundred thirty-three pounds and a third. The traders uſually diſtinguiſh three degrees of quality, by the names of head, belly and foot, according to its purity and whiteneſs. Some add a fourth ſort, of extraordinary fineneſs, of which a few pounds only are imported to Canton, and ſell there at the rate of two thouſand dollars the pecul.

It has been generally ſuppoſed that the Chineſe mix the Camphor of Sumatra and Borneo with their own and the Japaneſe. But the truth ſeems to be that they purchaſe the former for their own uſe, from an idea of its ſuperior efficacy, and export the latter as a drug they hold in no eſtimation. It is certain that the common Camphor will evaporate till it wholly diſappears. Whereas that of Sumatra and Borneo, called native Camphor, though doubtleſs from its volatility it muſt be ſubject to ſome decreaſe, does not appear to loſe much in quantity from being kept.

Camphor oil is a valuable domeſtic medicine, much uſed by the Sumatrans in ſtrains, ſwellings and inflammations; the particles, from their extreme ſubtilty, readily entering the pores. It is not manufactured, undergoes no preparation, and though termed an oil is rather a liquid and volatile reſin, without any oily quality. To procure it, they make a tranſverſe inciſion into the tree, to the depth of ſome inches, and then cut ſloping downwards from above the notch, till they leave a flat, horizontal ſurface. This they hollow out, till it is of a capacity to receive a quart. They then put into the hollow a bit of lighted reed, and let it remain for about ten minutes, which acting as a ſtimulus, draws the fluid to that part. In the ſpace of a night, the liquor fills the receptacle pre-

[a] Hiſt. of Sumatra, p. 125. [b] Loureiro. [c] Hort. kew.

pared

pared for it, and the tree continues to yield a ſmaller quantity for three ſucceſſive nights, when fire muſt be again applied: but on a few repetitions it is exhauſted. An oil not much unlike this from the Camphor tree is procured from another tree by the ſame method. It is called *menia cayoo* or wood oil, and is uſed to rub on timber expoſed to the weather, to preſerve it from decay; and it is alſo boiled with the *dammar* to pay the bottom of ſhips and boats[c].

It is ſuppoſed by many that the Camphor tree of Borneo and Sumatra is different from that of China and Japan. Loureiro does not preſume to decide whether they be the ſame, but he affirms, from repeated experience, that there is no difference in the efficacy of the drug, whatever country it comes from.

Camphor is conſidered as one of the principal diaphoretics and antiſeptics, and as poſſeſſing a degree of anodyne or antiſpaſmodic power. It is a medicine of a ſubtle and penetrating nature, and quickly diffuſes itſelf through the whole habit. If taken in conſiderable quantity it produces an uneaſy ſenſation in the ſtomach: though it does not heat the body ſo much as might be expected from its taſte: on the contrary it often rather occaſions a ſenſe of coolneſs. In acute diſeaſes it is given from a quarter of a grain to one or two grains or more, in conjunction with nitre or other anti-inflammatory medicines of the ſaline kind. Hoffman obſerves that it anſwers beſt on the approach of a criſis, or in the decline; and that it ſhould be uſed with caution during the height of fever, where the heat is great and the ſkin dry; and the ſame caution, he adds, ſhould be obſerved in plethoric habits, &c. In chronical diſorders it is uſed more freely; and ſometimes is uſed in conjunction with opium. It is conſidered as a corrector of the irritating powers of Cantharides. Camphor alone has ſometimes been known to cure that peculiar ſpecies of ſpaſmodic diſorder called St. Vitus's dance. Camphor is alſo uſed in a diſſolved ſtate in ſpirit of wine, &c. as an external embrocation in rheumatic pains, paralytic numbneſs, &c. &c. it is alſo made an ingredient in many other preparations.

4. Loureiro deſcribes his L. Caryophyllus as a middle-ſized tree, with brachiate and ſomewhat ſpreading boughs. Leaves ovate-lanceolate, quite entire, with three terminating nerves, ſmooth, an inch and half long, dulky-green above, glaucous beneath, petioled, alternate and oppoſite, odoriferous, hardiſh. Flowers white, ſmall, corymb-racemed, terminating. Petals ovate-lanceolate, ſpreading. Style longer than the ſtamens. Berry ovate, ſmall, dulky red. Bark and root dulky red, having the ſmell and taſte of Cloves, whence Loureiro's trivial name. He allows that his L. Caryophyllus is not far removed from L. Culilaban of Linnæus, and it is probably the ſame.

Linnæus recommends the fructification to be examined, on account of the ſingularity of a Laurus having oppoſite leaves. But it appears that the leaves are not conſtantly oppoſite, and that the fructification is that of Laurus.

Native of the Eaſt Indies and Cochinchina.

5. Native of Jamaica.

6. This tree riſes by a ſtrong branched trunk to a very conſiderable height; the inward bark is of a light blood colour, and incloſes a ſtrong greeniſh timber, which has given occaſion to the trivial name of Linnæus, taken from Browne's generic appellation. Leaves ſmooth, with three conſiderable arched nerves, reſembling thoſe of the Camphor-tree in ſhape, ſize and texture. Fruit ſcattered up and down upon the branches, ſeldom exceeding a haſel nut in ſize.

Wood very tough and hard, anſwering better than any other ſort for the cogs in the rolls of a ſugar-mill. Generally eſteemed one of the beſt timber woods in the iſland of Jamaica, and uſed on all occaſions where ſtrength and durability are required[b].

Introduced in 1778, by Thomas Clark, M. D.—Browne calls it Greenheart or Cogwood tree.

7. This is a tree with ſpreading branches, rugged with raiſed dots, but without any pubeſcence, aſh-coloured. Twigs or ſhoots like the branches, but in a ſort of whorl. Leaves frequent towards the ends of the ſhoots, alternate, petioled, acuminate with a blunt point, quite entire with a reflex margin, paliurous, pale green above, glaucous beneath, or yellow, ſmooth, two inches or more in length. Petioles ſemicylindric, grooved above, ſmooth. Flowers on the ſhoots below the leaves, racemed, on very ſhort peduncles, one-flowered or bind, thick, aſh-coloured, half a line in length. Drupe ovate, a little attenuated at top, ſhint, very dark blue, ſucculent, ſmooth, the ſize of a pea, containing a blue juice. Nut the form of the drupe, ſtriated, ferruginous. Kernel whitiſh. The expreſſed oil is uſed for making candles in Japan, of which country it is a native.

8. Stem ſhrubby. Branches round, knobbed with the fallen leaves, aſh-coloured, wrinkled, ſmooth. Leaves oppoſite, on ſhort petioles, acuminate, ſmooth, two inches long. Flowers ſcattered at the ends of the ſhoots. Peduncles ſolitary, one-flowered, half the length of the leaves.

Native of Japan[a].

9. The Laurus or Bay has been celebrated in all ages, and hence is called *nobilis* by Linnæus. With us it appears as a ſhrub, but in the ſouthern parts of Europe it becomes a tree of twenty or thirty feet in height; much ſubject however in general to put out ſuckers. Leaves evergreen, of a firm texture, the largeſt from an inch and half to two inches in breadth in the broad-leaved variety, and from three to four inches in length, entire, on ſhort petioles, having an agreeable ſmell, and an aromatic, ſubacrid, bitteriſh taſte. Flowers dioecous, or male and female on different trees, in racemes ſhorter than the leaves, of an herbaceous colour. Corollas four-petalled in the male flowers, with from eight to twelve ſtamens. Berry ſuperior, ovate, fleſhy, dark purple almoſt black. Receptacle none except a ſmall tubercle at the bottom, whence a vaſcular band riſes on each ſide the whole length of the ſeed, which is large, ovate, ſlightly mucronate above[f].

Native of the ſouthern parts of Europe, and of Aſia. Ray obſerved it not uncommon in woods and hedges in Italy. Haller ſays it abounds in all the orchards about Moutru, near the lake of Geneva. According to Scopoli, it is found in the woods of Iſtria. Belſonius remarked it on mount Ida, and very large trees on mount Athos. Abbé Sr. Pierre obſerves that fine Bay-trees are no where more common than on the banks of the river Peneus in Theſſaly, which might well give occaſion to the fable of the metamorphoſis of Daphne daughter of that river. Pallas ſets it down as a native of the Cherſoneſus Taurica, &c. It is wild alſo in the South of France, Spain, Crete, and many parts of the Levant. In England, it was cultivated certainly in 1562, as we learn from Turner[g]; probably much earlier.

Mr. Miller makes three ſorts of the Sweet Bay.]

1. The broad-leaved Bay of Aſia, Spain and Italy, almoſt too tender for the open air in England; with leaves much broader and ſmoother than thoſe of the common ſort.

2. The Common Bay, ſeldom hurt with us except in very ſevere winters. Of this there are two varieties, one with plane leaves, the other with leaves waved on the edges.

3. The narrow-leaved Bay, with very long narrow leaves, not ſo thick as thoſe of the two preceding, and of a light green: the branches are covered with a purpliſh bark, and the male flowers come out in ſmall cluſters from the axils of the leaves, ſitting cloſe to the branches.

[It is to be found in the nurſeries with variegated leaves, and other trifling varieties are mentioned in the old authors.

The leaves and berries of this well-known ſpecies have an aromatic, aſtringent taſte and a fragrant ſmell: the berries are much ſtronger than the leaves: both are accounted ſtomachic, carminative, and uterine, in

[c] Marſden's Sumatra, p. 120—123. [b] Browne. [f] Hort. kew. [a] Thunberg. [g] Gerarde. [e] Hort. kew.

which intentions the leaves are infused and drank as a tea, and the eſſential oil of the berries adminiſtered on ſugar, or diſſolved by means of mucilages or in ſpirit of wine in the doſe of a few drops. The principal uſe of Bay leaves and berries however in the preſent practice is external; viz. for fomentations, &c. &c.

There is ſome confuſion among perſons ignorant of botany, between the Sweet Bay [1] what we now commonly call Laurel (Prunus Lauroceraſus), which is known only to more modern times in Europe. What we now call Bay was formerly called Laurel, and the fruit of it only named Bayes.

In Greek it is Δαφνη; in German, *Lorbeerbaum*; in Daniſh, *Laurbertræe*; in Swediſh, *Lagerbærstrad*; in French, *Laurier*; in Italian, *Allora*; in Spaniſh, *Laurel*; in Portugueze, *Loiro*, *Loireiro*; in Ruſſian, *Lawr* or *Lawra wse derewo*.

This is certainly the true *Laurus* of the Romans, and *Daphne* of the Greeks, deſtined to furniſh the Delphic wreath, to grace the head of the triumphant hero, to guard the gate of the Ceſars and the Pontifex maximus, to be placed on the houſes of the ſick, and to be worn on the head of the prieſteſs of Delphi, who alſo chewed the leaves, and threw them on the ſacred fire.

10. This is a large tree with aſcending branches. The branches, and particularly the ſhoots are tubercled with ſcars from the fallen leaves; they are alternate, curved inwards, wrinkled and ſmooth. Leaves ſcattered, acuminate with a bluntiſh point, quite entire, ſmooth, veined, reflex, four inches long. Petioles ſemicylindric, grooved, ſmooth, reflex. Flowers terminating, below racemed, above panicled. Panicle trifid. Ovate, red nectareous ſcales at the baſe of the filaments, which vary in number from ſeven to nine; ſix outer, and one, two or three inner: they are unequal, flat, and nearly equal to the calyx. Anthers compreſſed, four-celled. Germ roundiſh. Style very ſhort. Berry globular, ſmall, brown [2].

Native of Madeira; the Canary iſlands, Virginia, Japan, Cochinchina.]

Mr. Miller ſays it was brought from the Canary iſlands to Portugal, where it has been propagated in ſo great plenty, as to appear now as if it were a native of that country. In the year 1620 it was raiſed in the Farneſian garden from berries brought from India, and was ſuppoſed to be a baſtard ſort of Cinnamon.

[Loureiro obſerves that the wood is of a yellow colour, not heavy, good for building, but better ſtill for furniture. This wood is called *Vigniatico* in the iſland of Madeira, and is probably what is imported into England under the name of Madeira Mahogany. It is hardly to be diſtinguiſhed from Mahogany, except that it is ſomewhat leſs brown [3].

It appears from Rea's Flora, that it was cultivated here in 1665.

11. Native of Madeira and the Canary iſlands. Introduced in 1760, by Lord Adam Gordon [4].]

12. The Alligator or Avocado Pear grows to the height of thirty feet or more in the Weſt Indies, and has a trunk as large as our common Apple-trees; the bark is ſmooth, and of an aſh colour: the branches are beſet with pretty large, oblong, ſmooth leaves, like thoſe of Laurel, of a deep green colour. The flowers are for the moſt part produced towards the extremities of the branches. The fruit is the ſize of one of our biggeſt pears, incloſing a large ſeed with two lobes, included in a thin ſhell.

[The branches are very ſucculent and ſoft. The pulp of the fruit is covered with a tough ſkinny coat, and contains a large rugged ſeed, which is wrapped up in one or two thin membranous covers. This fruit is held in great eſteem in the Weſt Indies: the pulp is of a pretty firm conſiſtence, and has a delicate rich flavour; it gains upon the palate of moſt perſons, and becomes ſoon agreeable even to thoſe who cannot like it at firſt; but it is ſo rich and mild, that moſt people make uſe of ſome ſpice or pungent ſubſtance to give it a poignancy; and for this purpoſe, ſome make uſe of wine, ſome of ſugar, ſome of lime-juice, but moſt of pepper and ſalt. This fruit ſeems equally agreeable to the horſe, the cow, the dog and the cat, as well as to all ſorts of birds; when plentiful, it makes a great part of the delicacies of the negroes [5].

Native of the Weſt Indies. Cultivated in 1739 by Mr. Miller [6].]

13. In ſome ſituations near the ſea this riſes with a ſtraight large trunk to a conſiderable height; but in the inland parts of the country it is of an humbler ſtature. The leaves are much longer than thoſe of the common Bay, and are a little woolly on their under ſide; their edges are a little reflexed; the veins run tranſverſely from the midrib to the ſides. The male flowers come out in long bunches from the axils of the leaves; the female flowers in looſe bunches on pretty long red peduncles. Berries blue in red cups: [grow two and ſometimes three together. Theſe trees are not common in Virginia, except in ſome places near the ſea. In Carolina they are every where ſeen, particularly in low ſwampy lands. The wood is fine-grained, and of excellent uſe for cabinets, &c. Some of the beſt reſembles watered Satin, and is very beautiful [7].

Cultivated in 1739, by Mr. Miller [8].

Plumier, regarding it as a genus diſtinct from Laurus, gave it the name of *Berbonia* from Gaſton Bourbon, ſon of Henry IV. and uncle of Louis XIV.

14 to 21. All theſe ſpecies are natives of Jamaica [9].

17. This is called Loblolly Whitewood, or white Sweetwood. The berries are as large as Cherries, plump and black, and the cups pretty thick and ſwelling. The leaves and tender ſhoots make excellent fodder for cattle.

20. This grows to about twelve feet in height, is four inches in diameter near the root, and divides into a great number of branches near the top. Berries oblong, even, elliptic, ſeldom leſs than an inch in length: they are black, very ſucculent, and contain a ſingle two-lobed kernel, without any partial covering [10].

22. This is a ſmooth tree, with the branches and ſhoots in threes; branches round, knobbed, aſh-coloured, divaricated; ſhoots angular. Leaves ſcattered at the ends of the ſhoots, on very ſhort petioles, acuminate with a blunt point, obſcurely ſerrate with a reflex margin; ſhining above, with the midrib ſtanding out; pale underneath, ſmooth, from an inch to an inch and half in length. Flowers uſually ſolitary, but ſometimes two together. Fruit oblong, with the piſtil permanent.

Native of Japan.

23. Stem ſhrubby, very much branched. Branches in threes or thereabouts, wrinkled, tubercled, aſh-coloured, ſmooth, curved inwards. Shoots four, five or more together forming a ſort of umbel, angular, upright. Leaves ſcattered about the ends of the twigs, petioled, blunt, margined, nerved, ſhining above, paler underneath, ſmooth, an inch or more in length. Drupe, or rather berry globular, blue the ſize of a pea.

Native of Japan [11].]

24. This riſes with a ſhrubby branching ſtalk eight or ten feet high, covered with a purple bark. Leaves oppoſite, near two inches long and one inch broad, ſmooth on their upper ſide, but veined on their under, where they are rough. Berries red, nearly the ſize and ſhape of the common Bay-berry.

[Linnæus remarks that the fruiting peduncles are coloured.

Native of North America, in ſwampy lands. It was introduced in 1765, by Mr. John Cree [12].]

25. This riſes to the height of ten or twelve feet, dividing into many branches. Leaves near three inches long, and an inch and half broad, ſmooth on their upper ſurface, but with many tranſverſe veins on their

[1] Thunb. and Loureiro. [2] Hawkſw. voy. 2. p. 5. [3] Hort. kew. [4] Catesby. [5] Hort. kew. [6] Swartz. [7] Browne. [8] Thunberg. [9] Hort. kew.

under ſide. Flowers of a white herbaceous colour, with ſix ſtamina in each.

[Involucre ſeſſile, four-leaved, much reſembling that of Cornus, including five petioled florets, the length of the involucre. Proper calyx (or corolla) ſix-parted, yellow, with linear ſegments. Stamens eight or nine, the length of the calyx, appendicled on the ſides. Germ ovate, within the calyx. Style ſimple[a]. Number of petals and ſtamens uncertain; ſometimes eight of the former and twelve of the latter[b].

Native of Virginia; whence it was ſent by Baniſter to Compton Biſhop of London, and cultivated in his garden at Fulham in 1688, by Mr. George London[c].

This tree has been confounded with the true Benzoin tree, for which ſee *Styrax Benzoin*.]

26. The Saſſafras tree is commonly rather a ſhrub, ſeldom riſing more than eight or ten feet high. (It ſometimes however grows into a large tree.) The leaves are of different ſhapes and ſizes; ſome oval and entire, about four inches long and three broad; others are deeply divided into three lobes; theſe are ſix inches long, and as much in breadth from the extremity of the two outſide lobes; they are placed alternately on pretty long foot ſtalks, and are of a lucid green; they fall off early in the autumn, and in the ſpring, ſoon after the leaves begin to come out, the flowers appear juſt below them, on ſlender pedunclcs, each ſuſtaining three or four ſmall, yellow (greeniſh white) flowers, which have five oval, concave petals, and eight ſtamina in the male flowers, which are upon different plants from the hermaphrodite flowers. Theſe are ſucceeded by an oval berry, which, when ripe, is blue.

[Ehret, in the year 1735, obſerved the male flowers in the nurſery of Mr. Chriſtopher Gray at Fulham to have uſually nine ſtamens, with glands between them uncertain in their number. Theſe flowers had a ſimple ſtyle, a ſtigma variouſly conſtructed, and no germ. He alſo examined the female flowers in Mr. James Gordon's nurſery at Mile End, and found the petals ſmaller, ſix ſtamens with an uncertain number of glands, from three or four to nine, ſtyle ſimple crowned with its ſtigma, and a germ[d]. From this deſcription it appears that the two ſorts of flowers ſhould have been called imperfect hermaphrodites, rather than male and female.

Cateſby deſcribes the Saſſafras as a ſmall tree, the trunk uſually not a foot thick. The leaves divided into three lobes by very deep inciſures. In march bunches of ſmall five-petalled flowers coming forth, ſucceeded by berries, in ſize and ſhape not unlike thoſe of the Bay-tree, hanging on red foot-ſtalks, with a red calyx, reſembling that of an acorn: they are at firſt green, and when ripe blue.

This tree is deſcribed at full length in the ſecond volume of Nova Acta Nat. Cur. by Trew, who has there given an ample account of its Natural Hiſtory. He there obſerves that the male flowers have eight or nine ſtamens, and ſometimes as many as thirteen, and ſix glands; two to each inner filament: the female or rather hermaphrodite flowers only four ſtamens without any glands.

The wood of this tree, which is of a light and ſpongy texture, has a fragrant ſmell, and a ſweetiſh aromatic taſte, and with the bark, is much uſed in the Materia Medica. It gives out its virtues both to ſpirit and water, but moſt readily to the former.

Saſſafras is uſed as a mild corroborant, diaphoretic, and ſweetener, in ſcorbutic, venereal, cachetic, and catarrhal diſorders. Infuſions made in water from the cortical or woody part raſped or ſhaved, are commonly drank as a tea: and that, in ſome conſtitutions, from its fragrance, is ſaid to affect the head at firſt; which inconvenience ceaſes on continuing its uſe a little time. It is made an ingredient in ſeveral diet-drinks, both empyrical and ſuch as are uſed in regular practice.

Native of almoſt all America, commonly in a ſwaſhy ſoil, never in ſwamps. It was alſo obſerved by Loureiro in the north of Cochinchina near Tunquin. It has withſtood the cold of ſeveral winters at Mrs. Colliſon's at Peckham, Mr. Bacon's at Hoxton, Mr. Gray's at Fulham, Mr. Gordon's at Mile-end, &c. &c. and was cultivated before 1633, by Mr. Wilmot, at Bow[e].

A decoction of Saſſafras with ſugar was ſold in coffee-houſes at the end of the laſt century, under the name of *Bochet*[f]. There was a ſhop in Fleet-ſtreet for the ſale of it within theſe few years, and perhaps others. The bark has been ſubſtituted in America for ſpice. It is ſaid that bedſteads made of the wood will never be infeſted with bugs[g]. Loureiro remarks, that it is very proper for making cabinets in hot climates, on the ſame account, becauſe the ſmell repels inſects. Willdenow however doubts whether the Cochinchineſe Saſſafras be the ſame with the American.

27. This is a tree with the branches warted by the fallen petioles. Leaves alternate, quite entire, petioled, naked, paler underneath. Peduncles from the axils of the leaves ſolitary or in pairs, with three or four umbels, as in Cornus, many-flowered. Involucre four-leaved; leaflets the length of the umbel, ovate, concave, blunt, hirſute on the outſide. Pedicels ſhort, hirſute. Calyx minute, hirſute. Petals ſometimes ſmall, but in general none. Stamens twelve to fifteen, with the filaments hirſute on the outſide, ending in dilated anthers. Three or four corpuſcles pedicelled and peltate, ſhorter than the ſtamens; probably the nectaries. Germ oblong, rough-haired. Style longer than the ſtamens. Stigma peltate. It has the appearance of a Laurus, but perhaps it may be a ſpecies of Tomex.

Native of Tranquebar in the Eaſt Indies, whence it was ſent by König[h].

28. This is a ſmall tree, five feet high, very much branched, with an unarmed twiſted trunk. Leaves quite entire, with terminating nerves, ſmooth, alternate, duſky green above, pale beneath, petioled. Flowers white. Common calyx four-leaved; leaflets roundiſh, concave, the two outer ſmaller, hairy: containing five peduncled florets. Proper calyx none. Corolla ſix-petalled; petals ovate, concave, almoſt equal. Filaments nine, flattiſh, ſhorter than the corolla; the three inner biglandulat: anthers compreſſed, blunt. Germ ovate, ſuperior: ſtyle ſhort: ſtigma blunt. Berry ovate, juicy, ſmooth, red, ſmall. Root thick, vertical, many-cleft, brown, oily. The whole plant is extremely bitter, and has the taſte and ſmell of Myrrh; whence the trivial name.

Native of Cochinchina. The root is warm, diuretic, emmenagogue, antiputreſcent, and anthelmintic. A red oil expreſſed from the berries, and having the ſmell and taſte of the plant, is uſed by the natives in the itch, wounds, puſtules and putrid ulcers, againſt worms and inſects that attack the human body. Loureiro ſuſpects that this may be the plant which affords the true Myrrh.

29. This is a large tree, with ſpreading boughs. Leaves quite entire, flat, cortaceous, veined, petioled, alternate, duſky green. Flowers reddiſh white, in axillary corymbs. Calyx (or corolla) cup-ſhaped, coloured, ſix-parted, with oblong, upright ſegments. Nectary of ſix peduncled glands. Stamens nine, unequal, of which three are appendicled; all collected into three bundles. Anthers oblong, flattiſh, truncate, not opening longitudinally, but emitting the pollen by four holes. Germ roundiſh. Style filiform, equal to the ſtamens. Stigma blunt. Berry roundiſh, fleſhy, very ſmall.

Native of mountains in Cochinchina.

30. This alſo is a large tree with ſpreading branches. Leaves acuminate, quite entire, veined, pale, odorous, hard, ſhining, reflex, alternate. Flowers white in looſe racemes. Calyx (or corolla) fleſhy, lobed, ſharply ſix-cleft, inferior, permanent. Stamens nine, flat, widening above, and thence emitting four very ſlender filaments from four holes, with as many oblong, two-celled little anthers. Nectary glandiliferous. Berry oblong-ovate, black.

Native of Cochinchina in mountain woods.

[a] Linn. ſyſt. [b] Colden. [c] Raii hiſt. and hort. kew. [d] Eph. nat. cur. [e] Hort. kew. from Ger. emac. [f] Houghton's collections, 3. 65. [g] Catlin in med. acad. Amer. vol. 1. [h] Retzius.

This and the preceding have a great affinity with Ocotea guianenſis of Aublet, 780. t. 310.—Poroſtema of Schreber, n. 1226.

31. This is a middle-ſized and very branching tree; the branches ſpreading. Leaves quite entire, flat, ſhining, two inches long, alternate, petioled. Flowers white, on one-flowered, lateral peduncles. Common calyx four-leaved: leaflets roundiſh, concave, coloured, deciduous; containing five florets. Petals ſix, roundiſh, ſpreading, unequal, with the border bitten. Nectary of ſix, ſeſſile, oblong, reflex glands. Filaments nine very ſhort, ſix declining to the petals, the other three upright, without glands. Six of the anthers compreſſed and ſquare, with four oblique cells. Germ roundiſh, ſuperior. Style none. Stigma ſimple. Berry globular, black, peduncled, very ſmall. Seed globular.

Native of Cochinchina, and probably alſo of China.

Berries corroborant, cephalic, ſtomachic and carminative. A decoction of them is of ſervice in the vertigo, hyſterics, palſy, &c. The bark has the ſame qualities, but in an inferior degree. The natives uſe the freſh berries as a ſauce for fiſh. The ſmell is fragrant: the taſte aromatic and warm. They have the ſize, colour and form of Black Pepper; and being faſtened to a long ſlender peduncle, are not unaptly called *Piper caudatum* or tailed Pepper.

The fruit having the form, ſize and quality of the Cubebe, Loureiro ſuppoſes this to be the tree which produces it: but the Cubebe is repreſented as a climbing plant, and the younger Linnæus decides that it is a ſpecies of Pepper.

32. This is a large tree with ſpreading branches. Leaves acuminate, quite entire, ſcattered, petioled, five inches long. Flowers polygamous, greeniſh yellow: in the hermaphrodites, calyx ſpreading bell-ſhaped, ſix-cleft, with ſharp ſegments. Filaments nine, awl-ſhaped, ſhorter than the calyx, very hairy; with oblong, two-celled, incumbent anthers. Germ roundiſh. Style thick, equal to the calyx. Stigma bifid, reflex. Berry globular, coriaceous, ſmall. Male flowers on a diſtinct plant, with a ſix-leaved calyx; the leaflets ovate, concave, lanuginoſe. Filaments nine, ſhort, hairy, with flat, four-celled anthers.

Native of mountain woods in Cochinchina.

The wood is yellow, durable, and fit for building or turning[1].

This ſpecies reſembles the 27th deſcribed by Retzius[2].

Loureiro remarks, that in all the ſpecies of Laurus which he found in India, he obſerved always hermaphrodite flowers, berries and not drupes, and the leaves perennial: but the latter circumſtance is common to almoſt all trees in the torrid zone.]

PROPAGATION AND CULTURE.

1, 2. Cinnamon and Caſſia are not ſo tender as moſt perſons imagine, and the tender treatment of the plants brought to England has generally deſtroyed them. Great heat is certainly prejudicial to them; when the plants therefore have taken new roots in the pots or tubs, they ſhould in ſummer be placed in a glaſs-caſe, where they may have plenty of air in warm weather; and in winter they ſhould be placed in a ſtove moderately warm.

3. In Europe this tree is propagated by layers, which are generally two years, and ſometimes longer, before they take root, ſo that the plants are very ſcarce; and as all thoſe which I have ſeen flower are male trees, ſo there can be no hopes of procuring ſeeds from them here: but if the berries of this, and alſo of the Cinnamon-tree, were procured from the places of their growth, and planted in tubs of earth, as is directed for the Saſſafras-tree, there may be a number of theſe plants procured in England: and if they were ſent to the Britiſh colonies in America, they might be there cultivated, ſo as to become a public advantage; eſpecially the Cinnamon-tree, which will grow as well in ſome of our iſlands in the Weſt Indies, as it does in the native places of its growth, and in a few years the trees might be had in plenty, for they propagate eaſily by the berries, as the French experienced in their American iſlands. The Portugueze brought ſome of the Cinnamon-trees from the Eaſt Indies, and planted them on the iſland of Princes, on the coaſt of Africa, where they now abound, having ſpread over a great part of the iſland.

The Camphire-tree does not require any artificial heat in winter, ſo that if it be placed in a warm dry green-houſe it will thrive very well. During the winter ſeaſon it muſt be ſparingly watered, and in the ſummer be placed abroad in a warm ſituation, where it may be defended from ſtrong winds, and not too much expoſed to the direct rays of the ſun. But during this ſeaſon it muſt be frequently refreſhed with water.

It may be propagated by laying down the young branches in autumn, which ſhould be treated in the ſame manner as is directed for L. Benzoin.

9, 10, 13. Theſe may be propagated by layers, and the common ſort (n. 9.) is generally propagated by ſuckers; but thoſe plants never keep to one ſtem, but generally ſend out a great number of ſuckers from their roots, and form a thicket, but do not advance in height; therefore the beſt way to have good plants, is to raiſe them from the berries, which they can be procured, for the plants which come from ſeeds, always grow larger than the others, and do not put out ſuckers from their roots, ſo may be trained up with regular ſtems. The beſt way is to ſow the berries in pots, and plunge them into a moderate hot-bed, which will bring up the plants much ſooner than if they are ſown in the full ground, and they will have a longer time to get ſtrength before winter; but the plants muſt not be forced with heat, therefore they ſhould be inured to bear the open air the beginning of June, into which they ſhould be removed, where they may remain till autumn; then the pots ſhould be placed under a common frame, that the plants may be protected from hard froſt, but in mild weather they may enjoy the free air; for while the plants are ſo young, they are in danger of ſuffering in hard froſt, even the common ſort of Bay. The ſpring following, thoſe ſorts which will not live in the open air, ſhould be each tranſplanted into ſeparate pots; but the common ſort may be planted in nurſery-beds ſix inches aſunder each way, where they may grow two years, by which time they will be fit to plant where they are deſigned to grow. The other ſorts muſt be conſtantly kept in pots, and ſhould every year be new potted, and as they advance in growth, they muſt have larger pots. As theſe plants require ſhelter in winter, a few of each ſort will be enough for a large green-houſe.

The common Bay will make a variety in all evergreen plantations; and as it will grow under the ſhade of other trees, where they are not too cloſe, it is very proper to plant in the borders of woods, where it will have a good effect in winter.

[Mr. Evelyn makes mention of Bay-trees thirty feet high, and almoſt two feet in diameter in the trunk. In the laſt century abundance of theſe trees were raiſed and kept in tubs, with curious round heads, and brought over here from Holland and Flanders[3]. In a warm dry ſandy or gravelly ſoil the Bay however will grow to the height of thirty or forty feet: but to ſecure its fine verdure it ſhould be planted in ſituations defended from north and north-eaſt winds, from which it ſometimes ſuffers in ſevere winters; generally however recovering in ſummer. The Bay ſhould never have a branch taken from it but in the ſpring. As a plant of elegance and beauty, yielding a moſt refreſhing and ſalubrious ſmell to a conſiderable diſtance, it cannot be too much encouraged[4]: and to perſons of claſſical taſte it can never fail to furniſh many pleaſing ideas, by recalling to their minds various fine paſſages and alluſions of the ancient poets.

The berries are ripe the end of january or beginning of february, when they ought to be gathered and preſerved in dry ſand till the beginning of march. Then, or as ſoon as the weather becomes favourable, on a ſhady border of rich looſe unlunged ſoil, made fine and well protected, drop the berries in rows fifteen

[1] Loureiro. [2] Willdenow. [3] Hought. collect. 3. 54. [4] Boutcher.

inches

inches aſunder, and four inches in the row, ſifting over them fine rich mould an inch thick. As ſoon as you perceive the plants to heave up the earth, refreſh them frequently but moderately with water, in the morning, when cold, in the evenings when mild weather, and continue to do ſo all the ſummer months. Let them remain two years, watering the ſecond ſummer.

Such as are intended to be increaſed by layers, may be laid down in march or auguſt; the latter is the beſt ſeaſon, and by the ſecond ſpring will make good plants.

The Bay will alſo grow by cuttings, but in the open ground ſlowly: in the beginning of april therefore prepare a moderate hot-bed of tanners bark, and cover it eight inches deep with rich looſe freſh earth. Plant the cuttings five inches deep, and eight or nine aſunder, rubbing off their leaves; water them gently every evening while the bed continues warm, and cover the glaſſes with mats during the heat of the day. When the cuttings have ſhot, let them receive all mild gentle ſhowers, and the evening dews. The beginning of auguſt the glaſſes may be taken off, and replaced when the weather begins to be froſty; keeping them open every mild day. The beginning of april following, or as ſoon as the weather becomes temperate, remove both glaſſes and frames; continue frequent and plentiful waterings during the ſummer months as the weather may require, and the ſucceeding april, the plants will be ſtrong, well rooted, and fit for removal.

The plants raiſed in any of theſe ways may now be removed to the nurſery; when having cut away their ſuperfluous roots and branches, attentively encouraging the leading ſhoot, plant them in a well-ſheltered quarter of light mould, in rows three feet and a half aſunder and eighteen inches in the row. Dig the ground autumn and ſpring; keep it clean, looſe and mellow in ſummer, and prune the plants annually in april. Let them continue three, but not more than four years, before they are planted out, where they are to remain.

The gold-ſtriped Bay is tender, commonly kept in pots, and houſed with hardy greenhouſe plants. It will ſtand in the open ground, but will be tarniſhed and ſometimes much injured in ſevere winters. It is a ſtrong rich variegation. The method of increaſing it is by budding it on the plain ſort.*]

The broad-leaved and narrow-leaved Bay are not ſo hardy as the common ſort, and will ſcarcely live abroad whilſt young, in common winters, without ſhelter. In ſevere winters the old trees are frequently killed, or at leaſt the branches are much injured. The plants therefore are frequently kept in tubs and houſed in winter: as are thoſe of the tenth or Indian Laurel always.

Although ſome plants of L. Borbonia have lived abroad in a mild winter, when planted in a warm ſituation, yet the firſt ſharp winter deſtroys them; they muſt be kept in pots or tubs therefore, and houſed in winter.

12. The Alligator Pear is propagated by ſeeds, which ſhould be obtained as freſh as poſſible from the countries of its growth; if they are brought over in ſand they will be more likely to grow than when dry. Set them in pots filled with rich light earth; plunge them into a hot-bed of tanner's bark, which ſhould be kept pretty warm; water them frequently but moderately when the earth appears dry. In five or ſix weeks the plants will come up; treat them very tenderly by keeping up the bed to a due temperature of heat; and when the weather proves warm admit the freſh air by raiſing the glaſſes a little. When they are about four inches high tranſplant them carefully, and where there are ſeveral plants in one pot, part them, preſerving a ball of earth to the root of each, and put them into ſeparate ſmall pots filled with light rich earth, which plunge into a hot bed of tanner's bark, ſhading them until they have taken new root; after which freſh air ſhould be admitted to them, in proportion to the warmth of the ſeaſon. Towards michaelmas the plants muſt be removed into the ſtove, and plunged into the bark bed, where during the winter ſeaſon they ſhould be kept in a moderate warmth, and muſt be gently watered twice a week. In the ſpring the plants ſhould be ſhifted into pots a ſize larger, and the bark-bed ſhould be then renewed with freſh tan, which will ſet the plants in a growing ſtate early, whereby they will make great progreſs the following ſummer. Theſe plants muſt be conſtantly kept in the ſtove, for they are too tender to bear the open air in this country at any ſeaſon, but in warm weather they ſhould have a large ſhare of air admitted to them.

24, 25, 26. Theſe three ſorts will live in the open air in England, but the Saſſafras is often injured by very ſevere froſts, eſpecially if it be in an expoſed ſituation; therefore theſe plants ſhould have a warm ſituation and a looſe ſoil; and in moiſt ground this, and alſo the twenty-fourth ſort, will thrive much better than in a dry ſoil; for when they are planted on a hot gravelly ſoil, they frequently die in ſummer when the ſeaſon proves dry. They are all of them now much cultivated in England, to add to the variety of ſhrubs, but they are not very ornamental plants; though indeed the Saſſafras makes a good appearance in ſummer, when it is fully clothed with its large leaves, which being of different ſhapes, makes an agreeable variety, when intermixed with ſhrubs of the ſame growth.

26. The Saſſafras-tree is commonly propagated by the berries, which are brought from America; but theſe berries generally lie in the ground a whole year, and ſometimes two or three years before they grow, when they are ſown in the ſpring; therefore the ſureſt method of obtaining the plants will be, to get the berries put into a tub of earth ſoon after they are ripe, and ſent over in the earth; and as ſoon as they arrive, to ſow the berries on a bed of light ground, putting them two inches in the earth; and if the ſpring ſhould prove dry, the bed muſt be frequently watered, and ſhaded from the great heat of the ſun in the middle of the day; with this management many of the plants will come up the firſt ſeaſon, but as a great many of the berries will lie in the ground till the next ſpring, ſo the bed ſhould not be diſturbed, but wait until the ſeaſon after, to ſee what will come up. The firſt winter after the plants come up, they ſhould be protected from the froſt, eſpecially in the autumn; for the firſt early froſt at that ſeaſon is apt to pinch the ſhoots of theſe plants, which, when young, are tender and full of ſap, ſo will do them more injury than the ſevere froſt of the winter; for when the extreme part of the ſhoots are killed, it greatly affects the whole plant.

When the plants have grown a year in the ſeed-bed, they may be tranſplanted into a nurſery, where they may ſtand one or two years to get ſtrength, and may then be tranſplanted into the places where they are to remain for good.

There have been ſome of theſe plants propagated by layers, but theſe are commonly two, and ſometimes three years before they put out roots; and if they are not duly watered in dry weather, they rarely take root; ſo that it is uncertain whether one in three of theſe layers ſucceed, which renders theſe plants ſcarce in England.

24. Willow-leaved Bay may alſo be propagated by ſeeds, when they can be procured, and by layers, which put out roots pretty freely.

25. The Benjamin-tree alſo, as it is falſely called, may be propagated by ſowing the berries. They generally lie long in the ground, ſo that unleſs they are brought over in earth, they often fail. But this may likewiſe be increaſed by layers, which put out roots freely, when the young ſhoots are made choice of.

Adulterina, Daun Salawar. *Rumph. amb.* 6. 58. *t.* 25. *f.* 1.
Leaves sickle-shaped, slightly crenate.]

DESCRIPTION, *&c.*

1. This rises with a shrubby stalk eight or ten feet high. The branches come out by pairs opposite; they are slender and covered with a whitish yellow bark. Leaves small, opposite, oblong, ending in acute points, pale green. Flowers in loose terminating bunches, gray or dirty white. Petals small, turning back at the top.

Native of India, Egypt, &c. The leaves of this shrub are much used by the Egyptian women, to colour their nails yellow, which they esteem an ornament. [Cultivated in 1739, by Mr. Miller[a].

2. This differs from the preceding in having the leaves on long petioles, somewhat jointed at the insertion; the calyx extremely small; the petals not flat and ovate, but linear, and having bent claws[b]. From this latter circumstance Forster gave it the name of *Acronychia*, from ακρος, *extremus* and ονυξ, *unguis*. But it does not seem to have any character to distinguish it from Lawsonia.

Native of New Caledonia: where it was found the 11th of September, 1774.]

3. This rises with a woody trunk eighteen feet high or more. The wood is hard and close, covered with a light gray bark. Branches alternate. Leaves oblong oval. At the joints where the leaves are placed come out single, strong, sharp thorns. Flowers in loose bunches from the sides of the branches, pale yellow, of a disagreeable scent.

[Loureiro describes it as eight feet high, with few, long, spreading branches, having a few straight spines terminating the shoots. Leaves broad-lanceolate, quite entire, sessile, opposite, subumentose, small. Flowers white, in racemed, terminating corymbs. Calyx bell-shaped, with acute, coloured segments. Petals curled and plaited, inserted into the calyx, than which they are somewhat longer. Stamens quickly falling.

Linnæus and Loureiro call the fruit a capsule, Gærtner names it a dry berry, globular flatted a little at top, crowned by the style, obscurely four-grooved, somewhat coriaceous, honey or ochre-coloured, four-celled. Seeds in each cell five to nine, variously angular, sharply pyramidal, ferruginous, suberose-barked. The pericarp does not divide into regular valves.

Native of the East Indies. Mr. Miller, who cultivated it in 1759, says that he received specimens of it also from the Spanish West Indies.

4. This shrub or small tree is six feet high, and very much branched. Leaves acuminate, smooth, petioled, scattered, strong-scented. Flowers white, in a racemed terminating corymb. Fruit a superior, roundish, small, four-celled berry, containing many seeds. The fruit has frequently three, two or even one cell only.

Native of Cochinchina.]

PROPAGATION AND CULTURE.

These plants are propagated by seeds, sown on a hot-bed early in the spring, that the plants when they come up may have time to get strength before winter. When the plants are fit to remove, plant each in a small pot filled with light sandy earth, and plunged into a hot-bed of tanner's bark, where they must be screened from the sun till they have taken new root. Then treat them as the Coffee tree, only giving them less water, especially in winter. They are too tender to thrive in the open air, they must therefore constantly remain in the stove, having plenty of air in hot weather.

[LAXMANNIA. *(From Erhart Laxmann, a Swede. Member of the Academy at Petersburgh, and Professor there. He travelled in Siberia.)*
Lin. gen. Schreb. n. 1746.
Cyminosma. *Gærtn. t.* 58.
Class. 6. 1. Hexandria Monogynia.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, bell-shaped, compressed, four-toothed, rather acute, inferior, very small.
COR. *Petals* four, linear, leathery, long, upright at the base, spreading, with inflected tip, a villose line on the upper part, two more approximated than the rest.
STAM. *Filaments* six, linear below, upright, awl-shaped at the tip, spreading, rather shorter than the corolla. *Anthers* roundish, affixed to the back.
PIST. *Germ* roundish, extremely villose. *Style* shorter than the stamens, thick, cornered. *Stigma* simple.
PER. *Berry* subglobose, tetragonal at the top, four-celled; the *cells* covered by a membrane.
SEEDS solitary, oblong, compressed.

ESSENTIAL CHARACTER.

Cal. one-leafed, four-toothed, inferior. *Cor.* four-petalled. *Berry* four-celled. *Seeds* solitary.

Gærtner describes the fruit under the name of Cyminosma Ankenda, and refers to Ankænda of *Hort. mal.* 23. and *Burm. zeyl.* 27.

Mr. Dryander remarks, that Gærtner's first species, *t.* 58. *f.* 2.—H, cannot be the same with Dr. Koenig's Jambolifera, as the petals are nearly of the same length with the calyx: the other species, which Gærtner describes with petals three times the length of the calyx, may perhaps be the same as Dr. Koenig's plant, and if so, it is figured in *Rheed. mal.* 5. *t.* 15. which figure agrees tolerably well with Dr. Koenig's specimen in regard to flowers and leaves, and as to fruit with Gærtner, *t.* 58. *f.* 1. Mr. Dryander has given the description of the flower from Koenig's manuscripts, which may be compared with Gærtner and with Schreber's character of Laxmannia above. He remarks that the four stamina, which alternate with the petals, have no doubt been taken for petals by Gærtner, who counts eight petals permanent below the fruit[c]. Possibly after all, this plant may be a species of Jambolifera. See *Calyptranthes*.

Forster has given the name of Laxmannia to a Synegenesious plant, which has the air of a Bidens.]

LAYING of Trees and Shrubs. This operation is thus performed:

First, having well dug the ground and made it very light, take some of the most flexible boughs, and lay them into the ground about half a foot deep, pegging them down with forked sticks, if necessary, leaving the

[a] Hort. kew. [b] Linn. suppl. [c] Linn. transf. 2. 313.

end of the layer a foot or a foot and half out of the ground; keep them moiſt during the ſummer ſeaſon, and they will probably have taken root and be fit to remove in autumn; or if not, they muſt remain another ſeaſon.

Secondly: Tie a piece of wire hard round the bark of the bough, at the place you intend to lay in the ground, and twiſt the ends of the wire, ſo that they may not untie, prick the part above the wire through the bark with an awl in ſeveral places, and then lay it in the ground as before directed. This method will often ſucceed when the other fails.

Thirdly: Cut a ſlit upwards at a joint, as is practiſed in laying Carnations, which by gardeners is called tonguing the layers.

Fourthly: Twiſt the part of the branch deſigned to lay in the ground like a withy, if it be pliable, and lay it in the ground as directed above.

Fifthly: Cut a circle almoſt round the bough that is deſigned to be laid half an inch, where it is to lay in the ground.

Though branches may be laid at any time, yet the proper ſeaſon for laying hardy trees that ſhed their leaves is october; for ſuch as are tender, the beginning of march; for evergreens, june or july.

When the boughs cannot be bent down into the ground, lay them in baſkets, boxes or pots, filled with fine mould mixed with a little rotten willow duſt, and elevated by blocks or treſſels. Too much of the head muſt not be left on; and the ſmaller the boughs are, the leſs way they ſhould be left out of the ground.

In trees of a hard wood, the young ſhoots, but in trees of a ſoft wood, the older boughs will take root beſt.

Many trees and plants will not put out roots from the woody branches, yet if the young ſhoots of the ſame year be laid in july, they will often put out roots very freely: but as theſe ſhoots will be ſoft and herbaceous, they muſt not have too much wet, which would cauſe them to rot; cover, therefore, the ſurface of the ground with moſs, which will prevent it from drying too faſt, and a little water will ſuffice.

[To raiſe trees by layers in quantity, a ſufficient number of trees muſt be headed down for ſtools, within a few inches of the ground, in autumn; and the ſummer following they will afford plenty of young ſhoots proper for laying in the autumn. In many trees, however, it will be better to wait two years.

The ground in the mean time ſhould be dug in winter; and conſtantly hoed, as the weeds riſe, in ſummer.

After the layers are taken up, the ſtools muſt have all the wounded parts taken away, and the old branches ſhould be cut off pretty cloſe to the ſtem: in the ſpring they will ſhoot out freſh branches, which may be laid the ſecond year after. Nurſerymen, who raiſe great quantities of trees this way, have two quarters of ſtools, to come in alternately, and furniſh a crop every year*.

2. Lechea major.
   Lin. ſpec. 133. *ſyſt.* 130. *Reich.* 1. 252. *amoen.* 3. 11. *f.* 4.
   Menandra ramis alternis. *Gron. virg. ed.* 2. 20.
   Leaves ovate-lanceolate, flowers lateral, wandering.
3. Lechea chilenſis.
   Lour. cochinch. 60.
   Leaves ovate-lanceolate, ſpathes three-flowered, terminating.

DESCRIPTIONS, *&c.*

1. Root fibrous, perennial, putting up ſeveral upright, ſimple ſtems, paniculed at top, and round. Leaves ſcattered, upright, quite entire, ſharp, above ſmooth and ſhining, beneath ſomewhat pubeſcent, with a reflex margin, on very ſhort petioles. Flowers numerous, on terminating, peduncled racemes.

Towards the root the branches are oppoſite or in threes; frequently alſo the leaves are in fours, ovate, and more hairy[a].

Capſule the ſize of the head of a ſmall pin, ovate-globular, very obſcurely if at all three-cornered, one-celled, half-three-valved; the valves marked within with a longitudinal, raiſed, deeper coloured ſtreak. Receptacle three ſhort linear ſcalelets, ſpringing from the middle of the baſe, and lying on the belly of the ſeeds. Seeds three, oblong, acuminate at both ends, three-ſided, convex on one ſide, angular on the other, obſcurely dotted, brown. It is conſtantly one-celled, and has no inner valves. The embryo is not circular, as in moſt of its congeners, but almoſt ſtraight[b].

Native of North America, Virginia, Canada.

2. Stems purpliſh, round, with ſimple, alternate, remote branches. Leaves alternate, rugged above, tomentoſe beneath, with a reflex margin, ſcarce manifeſtly petioled. Flowers two, three or four from the uppermoſt ſhoots[c]. Clayton aſſigns four ſtamens to the flower; the two upper ones approximating.

Native of North America, Virginia, Canada.

The plant deſcribed by Linneus for Lechea major is ſuppoſed to be Ciſtus canadenſis. But the plant intended by Kalm for Lechea major is very different, as may be ſeen by comparing the ſpecimens in the Bankſian herbarium.

3. Stem annual, manifold, creeping, ſhort. Leaves marked with lines, ſmooth, with ſheathing petioles. Flowers from a large blunt ſpathe. Petals blue, with claws. Styles three, equal to the ſtamens, with ſimple ſtigmas. Capſule ſuperior, three-lobed, three-valved, three-celled, with one ſeed in each cell. This plant ſeems at firſt ſight to be related to Commelina and Tradeſcantia, but it has not either villoſe filaments like the latter, or cruciate nectaries like the former. Native of China, near Canton[d].

DESCRIPTIONS, *&c.*

These are trees or shrubs, with alternate leaves; flowers in terminating spikes, and from the axils of the shoots; in the spikes alternate, on pedicels that have a single bractle at the base, and frequently two scales under the calyx. It is peculiar to this genus to have a pitcher-shaped body in the centre of the flower, which Linnæus calls the nectarium, inserted into the calyx below the petals, perforated in the middle for the passage of the style, shaped like a petal, coriaceous, entire at the edge, not staminiferous on the edge as in Pitigara (Gustavia) and Butonica, but covered on the inside with numerous subsessile stamens, and produced on the side into a membranaceous bilamellated strap. Calyx six-lobed at top, equal, the lobes deciduous. Petals six, inserted into the calyx under the divisions, and fastened to the nectary, coriaceous and concave. Germ half inferior, ending in a conical style, and a blunt stigma. Capsule woody, four-celled, but sometimes varying in the number of cells from two to six, differing in form, size and density; the vestiges of the calyx remain on it about half way down, at the top it is cut round, and furnished with a lid, which is produced or continued down into a central angular receptacle, and fastened to the partitions of the capsule. Seeds in each cell solitary or few, inserted into the receptacle, angular, covered by a membranaceous aril*.

1. This tree grows to a very large size (to the height of thirty feet). Leaves strong, thick, waved, seven inches long, and three inches wide, ending in a little point, midrib prominent the whole length underneath. Flowers at the end of the shoots from the axils of the leaves, and also from the branches and shoots themselves. The pedicel enlarges as it approaches the calyx, which is of a reddish colour on the inside. Corolla rose-coloured; two petals longer and wider, and four smaller. Capsule shaped like an urn, hard, woody, thick, about seven inches in height, four inches or more in diameter, and the opening of the cover two inches and a half, rounded next the pedunele, convex at top, and ending in a point; the remains of the calyx form a woody border, and above that is a collar near an inch high, which in the flower was covered by the claws of the petals. The periphery of the opening, which is closed by a lid or cover that descends the whole height of the collar, and often to the very bottom, is convex in its outer face, but the inner is produced into a long, woody, conical body, having several sides, to which are attached large oblong kernels, of an irregular shape, enveloped in a membrane, and very good to eat.

Native of the forests of Guiana; flowering in january, and fruiting in april. Called by the Caribbs *Canari Mokaque*, by the French *Marmite de Singe*, by Mons. Aublet *Quatele à grande fleur*.

2. This is also a very lofty tree. Flowers small, yellow, with two or three scales on the peduncle. Capsule the size of an egg, thin, hard and woody, in the form of a little oval pot; the cover is divided at bottom into four parts, to each of which an oblong, angular, bitter kernel is attached. This is eaten by monkeys. The Creoles call it *Petite Marmite de Singe*. Mons. Aublet names it *le Quatelé amer*.

There is a variety of it with a scale at the base of the peduncles, and the capsule compressed on one side.

3. This is not a very high tree. The boughs and twigs bend towards the ground. Leaves shorter than those of the preceding. Flowers much smaller, of a golden yellow colour, and smelling very sweet. Capsule small, thin, brittle; cover produced internally into a thin but strong wide partition, extending to the bottom of the capsule, and dividing it into two cells, in each of which is an oblong angular kernel, fastened to the upper part of the cell. The kernel being bitter, is eaten only by monkeys. Native of Guiana, on the banks of rivers.

4. This is a very lofty tree, the trunk attaining sixty feet in height and more, and being two feet and upwards in diameter. The bark rough and irregular. The wood white, except towards the middle, where it is red. The boughs extend every way at top, and the shoots are loaded with leaves ten inches long, two inches and a half wide, entire about the edge, smooth, strong, pale green, on a short petiole, which is convex underneath, and channelled above. Flowers at the extremity of the shoots in pendant racemes, on fleshy pedicels, thickening as they approach the flower, and having a deciduous scale at the base. Calyx cut into six unequal sharp, narrow, fleshy reddish segments. The corolla consists of six unequal petals, white, with rose-coloured edges, wide, very thick and fleshy at the claws; four smaller, and two larger. Nectary rose-coloured. Capsule thick, hard, woody, oval, rounded at bottom, convex at top, with a point in the middle, which is the remains of the style; it is about four inches in diameter, and five, six or more inches high. The cover falls off when the fruit is ripe; it is boxed into the hole of the disk that bears the stamens some lines in depth, and is produced into a woody, conical, angular body to the bottom of the capsule, which contains several oblong kernels, irregular in shape, and fastened to the different faces of this body. Immediately under the cover, towards the upper part, this capsule has a prominent border, marked by the six pieces of the calyx; and above this is a collar, which in the flower was covered by the claws of the petals, and which forms the periphery of the aperture when the cover has fallen off.

The

* Juſſieu.

The Portugueze turn boxes and other toys out of theſe capſules. The kernels are eaten; they are ſweet, delicate, and preferable to Almonds. (They are ſold in London under the name of Braſil nuts). Birds and monkeys feed much on them. On this account the Creoles of Cayenne call the fruit of this and the other ſpecies *Canari Makaque* or *Marmite de Singe*[a]. In Braſil they extract an oil from the kernels, which is much eſteemed. The Indians uſe the bark for making cordage, and as oakum for ſtopping the ſeams of boats. The wood being hard and durable, is excellent for mill-work. The capſules are made into drinking cups, pots, &c. Pilo relates, that a ſingle tree will yield fruit ſufficient to feed a moderate army.

Native of America; Braſil, Guiana. Introduced into the iſle of France before 1761, by M. le Comte d'Eſtaing.

5. This reſembles the preceding ſpecies in its leaves, and riſes to the ſame height. The trunk alſo is as large. Flowers axillary, at the ends of the ſhoots, on ſimple peduncles that bear ſeveral alternate flowers, having two ſcales at their baſe. Pedicels red, with ſmall whitiſh glands. Calyx veined with red. Corolla roſe-coloured. Capſule woody, an inch high, and an inch or more in diameter, rounded at the baſe, and convex at the top; about the middle it has a circular border, formed by the remains of the calyx, and above that a collar forming the opening, which is cloſed by a lid, convex, and terminating in a blunt point; within it has four cells, and a brown, oblong, bitter kernel faſtened to each.

Native of the foreſts of Guiana, and called Idatimon by the Caribbs.

There is a variety of this with yellow flowers[b].

6. This is an elegant, branching, upright tree, ſixty feet high. Leaves acuminate, ſerrate, ſmooth, ſubdiſtich, half a foot in length. Racemes terminating, and frequently an axillary flower at the uppermoſt leaves. Pedicels one-flowered, thick, very ſhort. Flowers large, the corolla and nectary white, the ſtamens and corpuſcles of the nectary yellow. Fruit very hard, brown, two inches in diameter. The cover falls off when the fruit is ripe; the dried pulp and ſeeds follow; but the pot or body of the capſule hangs on frequently two years in an inverted ſtate. The ſeparation of the cells is commonly incomplete, and in each there are two or three ſeeds, and ſometimes only one, in all about eight. Monkeys are fond of theſe, whence the inhabitants call the tree *Ollita de mono*. Jacquin relates, that having eaten a whole nut, he was ſeized with a nauſea in half an hour after, accompanied with a giddineſs of the head. The flowers are infeſted with a ſort of black waſp, which attacks thoſe who gather them. Native of woods about Carthagena in New Spain, flowering in June and July. The fruits are ripe in december[c].

Jacquin is of opinion that his L. minor is very different from the Lecythis of Loefling, and probably alſo from the Jacapucaya of Marcgraaf. Aublet ſuppoſes L. minor of Jacquin and L. Ollaria of Linnæus to be the ſame ſpecies, and diſtinct from Jacapucaya of Marcgraaf, n. 4.

LEDON. See *Ciſtus*.]

LEDUM (*a ladendo edore, from its diſagreeable injurious ſcent. Linn.*)

Leaves ovate-oblong, flat, ſmooth.

DESCRIPTIONS, *&c.*

1. Root branched, running widely and deeply into the ground. Stems ſhrubby, ſlender, three or four feet long, dividing into ſimple branches, and covered with a brown bark, which is tomentoſe or villoſe whilſt they are young, but afterwards becomes ſmooth. Leaves linear-lanceolate, duſky green above, and ſmooth, underneath covered with a brown pile, quite entire, reſembling thoſe of Roſemary, but wider, petioled, perennial. Flowers on pedunckes an inch or more in length, nodding before and after flowering, whitiſh, in axillary bundles or corymbs[a]. Capſule ſmall, obovate, terminated by a long permanent ſtyle: valves coriaceous; partitions membranaceous, ſpringing from the edges of the valves, doubled, opening at their inner angle by a longitudinal chink. Receptacles five, filiform, curved a little, ſpringing from the upper part of the axis of the fruit, and hanging down freely in the cavity of the cells. Seeds extremely numerous and ſmall, irregularly ſhaped like ſaw-duſt, pointed at each end, of a brownith ſtraw-colour[b].

Native of the North of Europe—β. Dwarf Ledum, of Hudſon's Bay. It flowers here in april and may. Introduced in 1762 by Mr. John Buſh[c].

Mr. Miller ſeems to confound it with Andromeda polifolia.

2. This ſhrub grows three or four feet in height, with a trunk as thick as a man's finger; branches the firſt years woolly and whitiſh, the ſecond tomentoſe and ruſt-coloured, afterwards ſmooth and brown. Leaves ſcattered alternately, on ſhort petioles, quite entire, perennial, blunt, an inch or an inch and half in length; when young pale green, hairy above and woolly white beneath, when older ſmooth, dark green, and ſometimes ruſt-coloured beneath. Common pedunckes terminating, ſcarcely an inch long, upright, covered with imbricate ruſt-coloured ſcales. Pedicels from each ſcale filiform, ſomewhat villoſe, corymbed. Flowers very like thoſe of the preceding, except in having only five ſtamens. In moſt of them, indeed, one fifth part is wanting in all the parts[d].

Native of Greenland, Hudſon's Bay, Labrador, Newfoundland and Nova Scotia. It flowers here in

[a] Aublet. [b] Ibid. [c] Jacquin.

[a] Krocker. [b] Gærtner. [c] Hort. kew. [d] Jacquin.

april and may, and was introduced in 1763 by Mr. Bennet[a].

Bees are very fond of the flowers of these plants. Animals do not browze on them, and they are reputed in some degree poisonous: they are, however, put into beer in order to inebriate. The smoke of them destroys bugs and other insects. The Russians are said to use them in tanning leather. A decoction is given in the itch, &c.[b]

3. This is a small shrub, scarcely a foot in height. Stem upright, roundish, rugged with scars, ash-coloured. Branches at stated intervals, in a sort of whorl, leafy or scarted, each subdivided and upright. Leaves like those of Box, scattered, frequent, on short petioles, blunt, two or three lines in length, somewhat wrinkled above, smooth beneath, dotted, shining on both sides, the edges rolled back. Corymbs of flowers terminating, simple, on one-flowered, pubescent peduncles. Bractes oblong, blunt, subimbricate, spreading. Calyx smooth, five-parted, five-cornered at the base; segments lanceolate, acute, erect. Corolla white; petals five, blunt, longer than the calyx, sessile, spreading. Filaments longer than the corolla, from upright spreading. Anthers purple, ovate, small, flattish on one side, twin and grooved on the other. Germ superior, grooved all round and rugged. Style cylindric, upright. Stigma simple, subemarginate, truncate. Capsule ovate, acute, somewhat wrinkled, three-celled, three-valved; the valves opening longitudinally on their inner side[c].

Native of New Jersey and Carolina in North America. Introduced in 1736 by Peter Collinson, Esq. It flowers in april and may[b].]

PROPAGATION AND CULTURE.

These shrubs growing on mosses or bogs, where the roots spread freely, cannot be preserved in gardens, at least so as to thrive, but in a proper soil and a shady situation. The plants must be procured from the places of their growth, and taken up with good roots; they must be planted in a border of bog earth, and frequently watered.

Leaves smooth, stem and peduncles scurfy.

3. Leea crispa. *Fringe-stalked Leea.*
Lin. syst. 855. *Reich.* 4. 149. *mant.* 124.
Stem angular fringed curled.

DESCRIPTIONS, &c.

1. This is a small tree resembling the Elder. Leaves like those of Sambucus canadensis, alternate, petioled, pinnate: divisions at the base nearer, often ternate, or even pinnate: leaflets oval-oblong, acuminate, serrate. Peduncles opposite to the leaves, usually trichotomous[a]. Berry marked with from three to six swellings, black, aromatic, containing from three to six seeds[b].

Native of the East Indies, Africa and New South Wales.

Gærtner has another species (vol. 1. 275.) which he calls *Aquilicia Otillis*, and suspects to be the same with Leea æquata (*n.* 2.) It differs, according to him, from Leea sambucina in the number of seeds, the pale colour of the berry, and the entire want of any aromatic flavour.

2. Stem round, pubescent. Leaves alternate, pinnate: leaflets in fives, petioled, lanceolate, acuminate, serrate, a span long, two inches wide, smooth, but when young pubescent underneath. Corymbs trichotomous. Native of the East Indies. Introduced before 177[c], by Mr. James Lee[c].

3. Root tuberous. Stem somewhat woody but annual, jointed, three feet high, with curled membranaceous angles. Leaves alternate, pinnate, with the rachis or midrib margined: leaflets petioled, three or five, oval-oblong, marked with lines, smooth, sharply serrate, with transverse nerves interwoven with parallel transverse streaks. Stipules solitary, under the leaves, semilunar, ciliate along the keel. Peduncle corymbed. Flowers snowy-white, very small. The nerves are opposite in both these species[a]. Native of the Cape of Good Hope. Introduced in 1767, by Mr. William Malcolm. It flowers in october[a].

LEERSIA. (*So named by Solander and Swartz. from John Daniel Leers, author of Flora Herborunensis.*)

Swartz. prodr. 21. *Lin. gen. Schreb. p.* 818.
Asprella. *Lin. gen. Schreb. n.* 105.

Lenticularia omnium minima arhiza. *Mich. gen.* 16. *t.* 11. *f.* 4.

Leaves in pairs, rootleſs.

DESCRIPTIONS, *&c.*

1. Stem dichotomous, filiform, divaricated, having a lanceolate leaf at the angle of the branches, but proliferous ones terminating the branches: that is, ſimilar leaves growing out of their ſides at right angles: where theſe three leaves are conjoined there ſhoots out a pen-

dent

* Swartz. * Aublet.

dent radicle, with a conical papilla at its base[a]. Linnæus obſerves, that the ſtems are flatted and proliferous, croſſing each other, and thus reſembling in the mode of growth Cactus Opuntia or Indian Fig. Dr. Witherling adds, that the leaf-ſtalks iſſue from the edge of another leaf, from a fiſſure parallel to the ſides of the leaf.

Native of moſt parts of Europe in ditches and ſtagnant waters; flowering from june to ſeptember.

2. The leaves of the common Duckweed are very ſmall, of a roundiſh ovate form, collected into heaps, by twos or threes, and forming extenſive green plats on ſtagnant waters, and covering the ditches; each leaf drops a ſingle radicle[b].

It is common in moſt parts of Europe, and flowers from june to ſeptember. Linnæus ſays in the Dog-days.

This plant affords nouriſhment not only to Ducks, but to the freſh-water Fly-type, Phalæna Lemnata, &c. Its quick and extenſive propagation makes it troubleſome in ſome caſes, but at the ſame time it muſt be conſidered that it arreſts a vaſt quantity of inflammable air from putrid water, and converts it into vital elaſtic air, adapted to reſpiration[c].

3. This differs from the preceding in having the leaves obovate, or narroweſt where they are joined together, the under ſurface ſlightly convex, and generally tinged with purple, the upper ſurface very convex, white, of a reticulated ſpongy appearance, and filled with water, ſomething reſembling the internal ſtructure of Scirpus lacuſtris, but not ſo regular[d]. Roots fibrous, from the centre of the under ſide of the leaf. Leaves three, four or five together, one growing out of the edge of the other[e]. Capſule two-celled, containing two ſeeds, ſomewhat compreſſed, and a little depreſſed in the middle, more globular when further advanced[f].

According to Gerard and Hudſon this is a mere variety of the preceding.

Native of ſeveral parts of Europe, in ditches and ponds; flowering in july and auguſt. Obſerved by Dr. Stokes in Worceſterſhire, ſept. 8, 1776.

4. The leaves of this are much larger than in the common ſort; they are thick, ſucculent, inflated, oblong-cordate, blunt, grooved above, bright green, ſmooth, purple underneath, five lines long, and four wide. This ſpecies is alſo diſtinguiſhed by its dropping packets of thick black fibres from the lower ſurface of the leaves[g]. The flowers are the ſame as in the preceding, but are placed differently; they are to be found between the duplicature of each lamina, on that ſide where one leaf inſinuates itſelf into the other. The fruit is larger and more flatted[h].

Linnæus ſays, it floats on the ſurface of the water on the appearance of the ſwallows, and ſinks again at their diſappearance. All the ſpecies ſink in the winter ſeaſon, and riſe again in the ſpring.

Native of moſt parts of Europe, in ditches, ponds, &c. flowering in july and auguſt.

5. Leaves very ſmall, the upper ſurface in front bright green, but the hinder part, with the lower ſurface, and roots purple; they have a longitudinal groove running along the middle which is forked in front, each branch running to the end of each lobe, and dividing them as it were in two. Native of the Eaſt-Indies[i].

6. This has commonly two leaves cohering together, one ſmaller than the other, and no roots[k]. This latter circumſtance makes it very probable that it is only Lemna polyrhiza in a naſcent ſtate, as Wiggers has obſerved.

Native of Italy and France.

Theſe plants are all annual, and float on ſtagnant water. Their flowers were obſerved in Italy long ſince by Micheli and Vaillant, but not being produced ſo freely in more northern climates, they were long thought by ſome to be cryptogamous plants. The fructification, however, has been well aſcertained by Ehrhart and Gmelin in L. gibba, by Linnæus in L. minor, and by Gmelin in L. polyrhiza[l]. Dr. Withering alſo, having examined ſome of them in a flowering ſtate, bears witneſs to the accuracy of Micheli's figures.

SPECIES.

1. Lemniſcia guianenſis.

Vantanea guianenſis. *Aubl. guian.* 572. *t.* 229.

DESCRIPTION, *&c.*

The ſtunk of this tree riſes from fifteen to twenty feet in height, and is a foot in diameter. The bark is brown and ſmooth. The wood white and compact. Abundance of twiſted branches ſpread in every direction. Leaves alternate, ſmooth, firm, entire, ovate, acuminate, on a ſhort petiole; the largeſt leaves are five inches in length, and two in breadth. Flowers at the ends of the ſhoots, very numerous, in large corymbs, on a woody peduncle. Corolla of a fine coral red.

Native of Guiana, where it is called *Jouantan*, whence Aublet has conſtructed its name. It flowers in auguſt[m].

Stem-leaf triternate, floral leaf biternate.]

DESCRIPTIONS, *&c.*

1, 2. These two plants have large tuberous roots about the size of those of Cyclamen, covered with a dark brown bark. Leaves on slender petioles from the roots, about six inches long. Those of the first are single, having many leaflets ranged along the midrib; but the petioles of the second are branched into three smaller; upon each of these are ranged several leaflets, in the same form as pinnate leaves. The flowers are on naked pedunclcs: in the first sort they are yellow; in the second they are smaller and paler.

Native of the islands of the Archipelago, and of the corn fields about Aleppo, flowering at Christmas. Here they do not flower till the beginning of april, and they do not produce seeds.

2. [This was cultivated before 1597, by Lord Zouch, as appears from Gerarde's herbal*. Rauwolf observed it about Aleppo; it has been found in several parts of the Levant: and Matthiolus says, that he remarked it in the fields of Tuscany, &c. and that it is common in Apulia.

3. Stem simple. Leaves triply-ternate, on long common petioles; the middle proper petioles shorter, the side ones scarcely any. Leaflets smooth, ovate, the middle ones often three-lobed. Raceme simple, terminating, loose, upright*.

Native of North America. Introduced in 1784, by Mr. William Young*.]

PROPAGATION AND CULTURE.

When seeds are procured from abroad (which should be sent in sand), sow them as soon as they arrive, and cover them with glasses in the winter. In spring, when the plants begin to appear, admit free air to them whenever the weather is mild. If they are not too close, let them remain unremoved till the second year; but where they are very close, take up a part of the roots in october, and plant them close to a warm wall; and in november lay some old tanner's bark over the surface, three or four inches thick. Take this off again in march, before the roots begin to push, leaving a thin covering to prevent the spring winds from drying the ground. These roots should have a dry loose soil, and must be seldom removed. October is the best time for removing them.

The plants are very difficult to preserve in England, for the roots will not thrive in pots; and in the full ground, the frost frequently destroys them in winter, especially when the roots are young. Before the severe winter of 1740, Mr. Miller had some of the roots in a south-west border, that flowered several years, without any shelter.

[These and most tender bulbs do best in a south border in front of a greenhouse or stove, covered with glasses.

4. Leontodon muricatum.
L'Herit. stirp. nov. 173. *t.* 82.
Leaves runcinate rugged, calyxes muricated imbricate loose somewhat reclining.

DESCRIPTIONS, *&c.*

Most of the species that were ranged by Linnæus under this genus have been separated by subsequent authors,

authors, on account of a difference in the calyx, down, and receptacle. Leontodon hiſpidum, hirtum, dantubiale, haſtile, tuberoſum, autumnale, pyrenaicum, alpinum, may be found under *Apargia*; and Leontodon tomentoſum is the ſame with *Tuſſilago albicans*. Perhaps none of the ſpecies but the firſt ought to have remained under this genus. The following are the generic characters of the three genera into which this has been ſeparated.

APARGIA. *Cal.* ſubimbricate with linear parallel unequal ſcales.
Down plumoſe, ſubſeſſile.
Rec. naked, ſubvilloſe.

HEDYPNOIS. *Cal.* calycled with ſhort ſcales.
Down none to the outer ſeeds: the inner have five, almoſt erect, awned chaffs.
Rec. naked.

LEONTODON. *Cal.* imbricate with looſiſh ſcales.
Down capillary.
Rec. naked, dotted.

Haller has L. Taraxacum and aureum only under the name of *Taraxacum*, and aſſociates moſt of the other Leontodons with *Picris*. Scopoli ſeparates theſe from Picris, and L. Taraxacum and paludoſa, under Fuchſius's name of *Hedypnois*. Wiggers diſtinguiſhes L. Taraxacum, by its ſtipitate capillary down, under the name of *Taraxacum*, and refers thoſe which have a ſeſſile plumoſe down to *Leontodon*. He would aſſociate L. paludoſum with *Chondrilla*, were it not for the difference of habit. But there is no end to reform in the genera of the claſs Syngeneſia.

1. Root perennial, tapering, milky, pale brown. Leaves varying from pinnatifid or deeply runcinate in a very dry ſituation to nearly entire in a very moiſt one, generally ſmooth, but ſometimes a little rough. A ſingle, large yellow flower is ſupported on a hollow milky ſcape, covered with a kind of down towards the top. Calyx ſmooth, glaucous; the ſcales perfectly ſmooth, the loweſt turning back. The flowers ſometimes contain more than one hundred and forty florets. Seeds a little crooked, flattiſh, ſomewhat four-cornered, ſtriated or grooved, prickly at top, of a pale olive colour. Down on a long ſtipe or foot-ſtalk, ſimple not feathered, ſhorter than the ſtipe. Receptacle naked, full of little holes[a].

Common all over Europe in meadows, on walls, dry banks, &c. A common weed in gardens.[b] It flowers from april to ſeptember. The flowers expand about five or ſix in the morning, and cloſe early in the afternoon[c]. As the flower advances the calyx is gradually preſſed out at top; when the flowering is paſt, it contracts again into a conical form; and finally, when the ſeeds are mature, the calyx is again puſhed back, and the aggregate of down aſſumes a ſpherical form, till the whole is looſened and diſſipated by the wind.

Early in the ſpring, whilſt the leaves are hardly unfolded, they are no bad ingredient in ſalads. The French eat the roots, and the leaves blanched, with bread and butter. Its diuretic effects have given it a vulgar name, not only in England, but other European nations. The expreſſed juice has been given to the quantity of four ounces, three or four times a day; and Boerhaave had a great opinion of the utility of this and other milky plants in viſceral obſtructions. When a ſwarm of locuſts had deſtroyed the harveſt in the iſland of Minorca, many of the inhabitants ſubſiſted upon this plant. Goats eat it, ſwine devour it greedily, ſheep and kine are not fond of it, horſes refuſe it; ſmall birds are fond of the ſeeds. Phalæna faſcelina and Thrips Phyſapus feed upon it[d].

Our common name of Dandelion is corrupted from the French *Dent de Lion*, which was given it from the toothing of the leaves.

Leontodon paluſtre ſeems ſcarcely to be any thing more than a variety. In this ſpecies which varies ſo much in the leaves, the having few notches or being even almoſt entire, can hardly be admitted as a ſpecific difference: and though the lower calycine leaflets are erect, yet finally they become reflex. The plant is ſmaller, neater, and more levigated and glaucous than the common Dandelion; but all this may be owing to ſituation.

2. Root tuberous. Leaves attenuate-petioled, ſubſpatulate[e].

Native of Montpellier and Italy.

3. Root perennial, end-bitter, the thickneſs of a reed or of the human finger, with long white fibres, white on the inſide, but uſually blackiſh without. Leaves all radical, ſometimes very few, ſometimes more, oblong, narrowing gradually towards the baſe, bright green, ſmooth on both ſides, unequally ſinuate-toothed, blunt ſometimes with a ſmall point. Scape one or two, round, ſtriated, upright, ſmooth below, but hiſpid towards the top with black hairs, and having a ſmall ſcale or two at different heights; it is from three to ten inches high, and has one flower at the top; ſometimes, but very ſeldom, there is a branch with a ſecond flower. The flower is elegant, each floret being yellow on the inſide but ſaffron-coloured on the outſide, both colours turning deeper. Calycine ſcales lanceolate-oblong, acute, erect, dark green, hiſpid with black hairs, with ſhort ſcales at the baſe. Seeds linear, with a ſeſſile, ſnowy-white, ſimple down[f].

Linnæus remarks, that it has the leaves of L. Taraxacum, but ſmaller and blunter. The ſcape naked and ſtriated, with a linear leaflet in the middle. The calyx brown, upright, rough-haired at the baſe, with the keels of the leaflets ciliate. The corolla tawny, red underneath. The receptacle villoſe.

This plant, having a ſimple down, cannot be an *Apargia*; and having the down ſeſſile, the ſcales of the calyx erect, and the receptacle villoſe, it is not a *Leontodon*.

Native of Switzerland, Auſtria, and Italy. Introduced in 1769, by Monſ. Richard[g].

4. The whole plant is rugged and milky. Root perennial, fuſiform, almoſt ſimple. Stems diffuſed, a foot and half high, branched, round, flexuoſe, ſomewhat ſtriated, muricated, milky, red. Branches alternate, reſembling the ſtem. Root-leaves proſtrate, petioled, longer: ſtem-leaves half-embracing, alternate, ſpreading: both having a red rib, villoſe-muricate, very rugged, from ſix to nine inches long, and two inches broad. Peduncles one, two or three, one-flowered, almoſt upright, the length of half the plant, round, muricated, bracted. Flowers yellow, two inches in diameter. Seeds narrow-oblong, ſharp at both ends, ſtriated, rufous. Down ſtiped, feathered, ſpreading. Receptacle naked, flat, dotted.

The flowers are not radical as in Leontodon, it has leaves like it, but the whole plant is muricated. It has the calyx of Scorzonera tingitana and picroides, but the down is ſtiped. It differs from Crepis in having an imbricate calyx[h]. It has the ſtiped down of Leontodon; but it is feathered or plumoſe, as in Apargia.

Native of the coaſt of the Mediterranean near Tunis and Algiers, where it was firſt obſerved by René Louiche Deſfontaines[i].

Ballote inodora, foliis Coronopi. *Amm. ruth. n.* 60. *t.* 8.

Leaves three-parted multifid linear blunniſh.

DESCRIPTIONS, &c.

1. The root ſeems to be perennial, though moſt authors mark it as biennial. Stem upright, hard, from two to three feet in height, grooved, pubeſcent at the angles and joints, branched, frequently purple. Leaves lanceolate and acutely three-lobed, with ſome notches beſides; uppermoſt undivided; loweſt very much and obtuſely lobed and broad, ſomewhat like thoſe of the Gooſeberry. Whorls of flowers numerous. Corolla whitiſh on the outſide, elegantly ſtained with paler and darker purple within. Calyx ſtreaked with five green lines, and every outer one ſubtended by a ſetaceous bractæ. Filaments hairy. Anthers brown, before they burſt ſprinkled with white globular points, looking like enamel. Linnæus chiefly diſtinguiſhes the genus from Phlomis by this minute circumſtance.

The herb is bitter and tonic, with no very pleaſant though pungent ſmell. It was formerly uſed in the cardialgia, whence its old name, but it is now become wholly obſolete, except perhaps among cow-leeches and farriers. Bees are fond of the flowers.

Native of many parts of Europe on banks or under hedges, in a gravelly or calcareous ſoil. Near Combe wood, Surrey[a]. Oxfordſhire, Cambridgeſhire, Norfolk and Suffolk; Monmouthſhire.

Motherwort in German is called *Herzgeſpann* or *Herzkraut*. In Daniſh, *Hiertespan*. In Swediſh, *Benaſſla*. In French, *Agrimoine, Cardiaque, la Cordiale*. In Italian, Spaniſh and Portugueze, *Agripalma, Cardiaca*.

2. This is a biennial plant. Stems ſeveral, from two to three feet in height, upright, deeply hollowed on each of the four ſides, ſmooth except at the joints, where they are hairy. Branches ſcarcely any at bottom, but deceaſſately oppoſite at top, ſlender, the length of a foot and more. Internodes a hand and half, a hand, or leſs in length. Leaves very much wrinkled, tomentoſe, ſoft, pale green, reflex, unequally ſerrate with ſharp ſerratures, but entire at the baſe of the leaf and the origin of the lobes, acuminate, oppoſite. Lower ſtem-leaves very large, roundiſh, five-lobed or ſometimes ſeven-lobed; lobes ſub-ſerrate, ovate-oblong, approximating, bent back variouſly, the middle one trifid, the next biſid, the reſt multifid; the upper leaves and thoſe on the branches wedge-ſhaped, three-lobed, the lobes ſeldom divided, acuminate, the uppermoſt undivided but ſerrate. Petioles three times the length of the leaves, channelled, horizontal or declining. Whorls very numerous, terminating, diſtant, compoſed of many axillary flowers heaped together in four diviſions. Involucres briſtle-ſhaped: briſtles almoſt preſſed cloſe, to each diviſion five, ſhorter than the calyx, green, and below them a leaf on each ſide. Flowers ſeſſile, white. It is very nearly allied to the preceding; but that is of a darker green and more hirſute, the ſtems are not only hairy at the angles but over the whole ſurface, the ſides are flatter, the branches more ſpreading, and of a duſky purple colour. Leaves narrower, the margin of the whole leaf and of the lobes ſtraighter, perfectly flat and not reflex at the edge; the uppermoſt trifid, not at all ſerrate, and the reſt leſs ſerrate, with the ſerratures ruder and more equal; the lobes alſo of the ſub-axillary leaves ſo narrow as not to cover each other, and blunter. Whorls more numerous, and nearer, with larger and diſtant bractes. Flowers ſmaller. Calyx duſky-red. Corolla pale red, ſeldom white, with the upper lip narrower, leſs tomentoſe. The upper end of the ſeeds obtruncated, ſmooth or ſubtomentoſe, not hirſute[b].

Native of Switzerland and the South of France. Ray had it from London before the year 1686. Mr. Miller aſſerted, before 1759, that having frequently raiſed it from ſeed, it was a diſtinct ſpecies from the common one.—In the Kew catalogue (3. p. 494.) it is ſaid to be a native of Siberia, and to have been introduced in 1784, by William Pitcairn, M. D.

3. This is an annual or biennial plant, with ſomething of the ſame ſmell with Lamium. From a branched, fibrous, whitiſh root, a ſtem riſes three feet in height, (and even almoſt twice as high in gardens) upright, leafy, branched. Leaves petioled, acuminate, veined: the lower leaves in the cultivated plant rounded-ovate and wide. The ſtem, branches, calyx, corolla, and back of the leaves are ſoft with villoſe hairs, ſcarcely viſible without a glaſs. There are about twenty flowers in a whorl, they are ſmall, and are ſupported by a many-leaved involucre of ſetaceous ſpiny bractes. The toothlets of the calyx end in a ſtiff ſphinle. Corolla fleſh-coloured: throat long, very much curved inwards above the tube: upper lip rounded: lateral ſegments of the lower lip half-ovate; the middle one twice as wide and roundiſh. Anthers ſubovate, dirty green, twin, cylindric, without any of thoſe ſhining dots which Linnæus gives for the eſſential character[c].

Linnæus adds, that the calyx is five-cleft and awned,

[a] Engl. bot. Relh. Lightf. Wither. [b] Murray.
[c] Jacquin.

that there are awns also under the whorls; that the corolla is scarcely longer than the calyx, like that of *Nepeta*, with the helmet or upper lip entire, and the middle segment of the beard or lower lip not crenate.

Loureiro says that the flowers are saffron-coloured, and that he remarked the little shining, raised, subglobular dots scattered over the anthers, which he found to be the vesicular conglobate pollen, separately or in small particles jointly shining on the germ, the filaments, and the inside of the tube of the corolla, on which it fell.

Native of Austria, and in Hungary more abundant[a]. In Bohemia, the Ukrain, Germany, and even Java[a]. In Piedmont[b]. On the eastern coast of Africa in Zanguebar[c]. Cultivated in Chelsea garden in 1713. It flowers from june to august[a].

4. This is a biennial plant. It differs from the common sort in having the leaves divided to the petiole, and the segments of the leaves under the whorls commonly serrate and gashed[d]. Corolla flesh-colour: upper lip erect, vaulted, covering the filaments: lower lip trifid, the lateral segments approximating to the upper lip, the middle one obcordate[e].

Native of Russia. Gmelin says it grows all over Siberia. Mr. Miller received the seeds from Dr. Amman of Peterburgh, and cultivated this plant in 1756. He says, there are two distinct varieties, one with smooth stalks and leaves, and the other very hairy[f]. Linnæus also remarks that the plant from the East Indies is more smooth.

5. This also is a biennial plant. Stems several, from eighteen inches to a yard in height, tinged with purple: branches seldom more than two or three pairs. Flowers in close whorls, the lower three or four inches from each other, the upper much closer; corolla red, the outside paler and hairy; filaments red. Structure of the flower as in the common Ballote. Under each whorl two soft leaves, divided like those of Coronopus, into three principal segments, the lower wider and cut into more parts, the upper narrower and seldom subdivided, sometimes having violet-coloured spots on them[g].

Gmelin affirms that it is a mere variety of the preceding, with much larger flowers, and the upper lip almost equal to the lower.

Native of Siberia and China.

Mr. Miller cultivated it in 1759[a]. Probably intending in the eighth edition of his Dictionary to remove these plants from Cardiaca, under which name the first, fourth and fifth stand in the seventh edition, to Leonurus, he has there omitted them wholly. He says, that the seeds of L. sibiricus were sent him from Venice by the Chevalier Rathgeb, who received them from Istria. The two species, under the name of Leonurus in the eighth edition of the Dictionary, belong to the genus *Phlomis*.

PROPAGATION AND CULTURE.

2. These plants, when once planted in a garden, will soon multiply, especially if the seeds be permitted to scatter. The roots will continue many years.

3, 4, 5. These rise easily from seeds, sown in the spring upon a bed of common earth, and require no other care, but to keep them clean from weeds, and thin them where they are too close. In autumn they may be transplanted where they are designed to flower and seed, and require no farther culture.

LEONURUS. See *Galeopsis* and *Phlomis*.

LEOPARD'S-BANE. See *Doronicum*.]

LEPIDIUM, (*of Pliny, Ἀνάβασις of Theophrastus; from* λεπὶς, *a scale.*)

Lin. gen. n. 801. *Reich. n.* 865. *Schreb. n.* 1077. *Gærtn. t.* 141. *Juss.* 241. *Tournef. t.* 103.

Nasturtium. *Tournef. t.* 102.

Class. 15. 1. Tetradynamia Siliculosa.

Nat. order of *Siliquosæ* or *Cruciformes*. *Cruciferæ*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* four-leaved: *leaflets* ovate, concave, deciduous.

COR. four-petalled, cross-shaped. *Petals* obovate, twice the length of the calyx: with narrow *claws*.

STAM. *Filaments* six, awl-shaped, length of the calyx, the *two opposite* ones shorter. *Anthers* simple.

PIST. *Germ* heart-shaped. *Style* simple, length of the stamens. *Stigma* obtuse.

PER. *Silicle* heart-shaped, emarginate, compressed, sharp on the margin, two-celled: *valves* navicular, keeled, opposite the lanceolate *dissepiment*.

SEEDS some, ovate-acuminate, narrower at the base, nodding.

OBS. *In* Nasturtium. Tourn. *the pericarp is sharp on the margin, and commonly more emarginate at the tip.*

In Lepidium. Tourn. *the pericarp is obtuse on the margin, and not emarginate at the tip.*

Iberis *has a difformous flower, which is unusual in this class: the* ruderale *is apetalous, and the* alpinum *is tetrandrous.*

ESSENTIAL CHARACTER.

Silicle emarginate, cordate, many-seeded: *valves* keeled, contrary.

Leaves elliptic-oblong acute quite entire, flowers tetradynamous.

DESCRIPTIONS, &c.

1. Root annual. Stem about a foot high, round, upright, ſmooth, tinged with purple, dividing into many ſlender branches. Root-leaves and lower ſtem-leaves, and ſometimes the loweſt on the branches bipinnatifid; with narrow, acuminate, flat ſegments: the next to theſe leſs divided have an entire embracing baſe: the upper ones are all quite entire, heart-ſhaped, embracing, ſome ſharp, others blunt: all glaucous, ſomewhat thick; ſome very ſmooth, others having hairs at the edge and on the upper ſurface, viſible only with a glaſs. Flowers in corymbs, or long looſe ſpikes from the ends of the branches; they are ſmall and compreſſed: calycine leaflets blunt, upright, yelloviſh green, two oblong, the other two twice as broad and ovate: petals ſpatulate, narrow, yellow, flat, blunt, a little

little longer than the calyx. Silicles orbiculate, compreſſed, ſcarcely emarginate, and the terminating ſtyle ſo ſhort as to be ſcarcely obſervable; they are ſmooth, and there is a ſingle ſeed of a bay colour in each cell [a].

Native of Auſtria and the Levant. Cultivated in 1640, according to Parkinſon. It flowers in july [b].

2. Leaves like thoſe of Iberis vulgaris. Flowers white. Silicles ſmall, acuminate, containing a ſingle ſeed in each cell. It is an annual plant, native of Iberia and Media, in dry places. It flowers there in july and auguſt [c].]

3. This is a ſmall annual plant, [with many linear root-leaves, pinnatifid or toothed at the top, tender, ſmooth,] ſpreading on the ground. Among theſe riſes a naked ſtalk, two or three inches high, terminated by five or ſix ſmall white flowers, [with equal petals. Silicles flatted, emarginate,] incloſing four or five roundiſh ſeeds.

[Gouan mentions a variety with all the leaves cordate-ovate on long petioles; and ſays that he has often remarked ſix ſtamens.

Native of Spain and the South of France. Cultivated by Mr. Miller in 1768. It is diſtinct from *Iberis radicaulis*.

4. This alſo is an annual plant. Some of the leaves are ovate and entire, others three-lobed, five-lobed, lyrate. Scapes radical, and ſome peduncules from the ſtem, longer than the leaf. Calycine leaflets concave. Petals wedge-ſhaped, white, not longer than the calyx. Stamens ſix. Style ſcarcely any. Silicle like that of *Draba verna* [d].

Allione remarks, that the ſtems are not really naked, but leafy, and that the miſtake has ariſen from the leaves falling off very eaſily.

Gouan affirms, that the ſpecimens of L. petræum, which he received from Haller and Jacquin, differed in nothing from this.

Native of the South of France and the county of Nice.

5. Root perennial, ſlender. The whole plant is ſmooth, and has the ſame taſte with Creſs. Stems very ſhort, clothed with alternate leaves, putting out round, upright ſcapes, from one to two inches long, with flowers in a corymbed raceme. Leaves thick, the firſt ſimple, ovate-roundiſh, and wider; the next trifid, with the end one larger; the reſt pinnate, with two or three pairs of leaflets, and an odd one frequently a little larger; leaflets quite entire, lanceolate. Calycine leaflets ſomewhat oblong, ſpreading very much. Petals milk white, quite entire, wide. Stamens always ſix, tetradynamous. Germ ovate-oblong. Style ſhort, crowned with a blunt thickiſh ſtigma. Silicle ovate or lanceolate, compreſſed, with the ſtyle at the end. Seeds few [e].

Native of the Alps of Germany, Switzerland, and Italy. Introduced in 1775 by Doctors Pitcairn and Fothergill. It flowers from april to june [f]; in the Alps from may to auguſt.

6. Root biennial (annual, *Lin. Jacqu.*) taper and fibrous. Stem much and alternately branched (from near the root, ſpreading. Leaves dark green, elegantly pinnate, or rather very deeply pinnatifid, with an odd lobe; the ſegments oval or ſpatulate, more or leſs pointed, entire, ſmooth, (from ſix to twelve pairs.) Flowers in a cloſe corymb, gradually lengthening out into a ſpike, very minute, erect. Calyx and corolla ſpreading: calycine leaflets ovate, concave. Petals ſomewhat obovate, but narrow, about the length of the calyx or ſhorter, ſometimes but not always ſlightly notched at the tip. Stamens ſix, of which from the ſmalneſs of the flower, the inequality can ſcarcely be perceived, but the ſhorteſt ſtand remote from the others. Silicle exactly oval, flat, with the remains of the ſtyle in a minute notch at the tip, ſmooth; valves with a ſharp but not dilated keel. Seeds two in each cell, on ſlender footſtalks. This has the proper ſilicle of a *Lepidium*; in ſome of the foreign ſpecies it approaches ſo to that of *Thlaſpi*, that it is ſcarcely poſſible to define the limits of the two genera [g].

[a] Jacquin. [b] Hort. kew. [c] Boxbaum. [d] Linn. mant. [e] Jacquin. [f] Hort. kew. [g] Engl. bot.

Native of ſeveral parts of Europe, as Oeland, Auſtria, Switzerland, Dauphiné, Sileſia, England, and according to Loureiro, of China. With us it is found on St. Vincent's rocks and walls near Briſtol, at Uphill in Somerſetſhire, near Pembroke, &c. flowering in march and april.

7. This is a biennial plant. The root-leaves bear a great reſemblance to thoſe of Cardamine, whence the trivial name: they have three or five pairs of ovate leaflets, the end one larger than the reſt. Stems a ſpan high, branched, terminated by a raceme of white flowers. Stem-leaves ſmaller, compoſed of five leaflets, the odd one larger and ovate.

Native of Spain, by way ſides in a dry clay ſoil [a].

8. This is an annual plant. Root-leaves pinnate, petioled, decurrent; lower leaflets roundiſh, creſcent-ſhaped, palmate in front; outer much larger, outwardly ſemipinnatifid with linear ſegments, the odd one entire. Stem-leaves few, linear, erect, ſcarcely divided. Stem a ſpan high, ſtiffiſh, thickiſh, awl-ſhaped, branched at bottom: branches awl-ſhaped, quite ſimple, ſtiff, ſpiny at the end. Flowers ſcattered, white, on a very ſhort ſtiff pedunele. Calyx ſmall, ovate, upright, gaping, pale, deciduous. Petals obovate, twice as long as the calyx, ſpreading between the ſegments of the calyx. Stamens white, ſimple, the length of the calyx. Silicle wedge-form, bifid, ſtiff, compreſſed at the tip, ſubſeſſile.

Native of the Levant [b].

9. Root annual, white, fuſiform, ſlender. Stem upright, round, ſmooth, from a foot to two feet in height, branched at top; both ſtem and branches terminated by looſe narrow ſpikes of flowers. Leaves oblong, alternate, pinnate, the pinnæ of the lower multifid, of the upper more entire, linear or lanceolate. Flowers ſmall. Calyx very ſmall, greeniſh. Petals white, larger than the calyx. Silicle roundiſh, without any ſtyle; the valves winged, whence Crantz makes it a *Thlaſpi*. Seeds ſmall ruſeſcent, ovate, marked with lines, having a ſharp taſte, like Muſtard [c]. According to Gærtner, the ſilicle is ovate, a little notched at each end, compreſſed; keel of the valves ending in a membranaceous margin: partition lanceolate, contrary to the valves. Seeds ſolitary, ovate, compreſſed a little, with a depreſſed line along the middle on each ſide, ſmooth, ferruginous or ſulvous, mucilaginous. He remarks, that thoſe ſpecies which have ſimple cotyledons and ſeveral ſeeds, may be referred to *Thlaſpi*; and ſuch as have one ſeed only in each cell to *Naſturtium*.]

Of the Garden Creſs, ſo much uſed in winter and ſpring ſalads, there are ſeveral varieties, one with broad leaves, another with curled leaves, and the common ſort. [Linneus remarks, that in the common ſort the leaves are multifid; that there is one variety in which they are lanceolate, entire and gaſh-ſerrate; and another in which they are pinnate and curled; but that no one can doubt their being of the ſame ſpecies who conſiders the fructification, ſtructure, taſte and appearance of the plants.

The native place of this commonly cultivated plant being unknown, Linneus ſuſpects it to have had its origin from *L. ruderale*, but this notion has not obtained credit. It is inſerted by Linneus, Krocker and Villars in their local floras.

The young plant has the ſmell and taſte of this natural order, but in a far inferior degree to Scurvygraſs; it may be however of ſome uſe as a diuretic and antiſcorbutic, if taken largely.]

10. This is a biennial plant. The lower leaves, which ſpread on the ground, are near two inches long, and about half an inch broad. Stalks a foot high, dividing into a great number of ſlender branches, having ſmall oblong leaves on them, which are cut on their ſides, and a little curled on their edges. The ſtalks and leaves are of a gray colour inclining towards hoarineſs. The flowers are produced in cluſters at the end of the branches; they are very ſmall and white, appear in july, and are ſucceeded by roundiſh bordered ſeed veſſels, which are compreſſed, and have one

[a] Linn. amœn. [b] Linn. mant. [c] Krocker.

small oblong seed in each cell, ripening in the autumn. Native of the Levant, and Spain. [Cultivated by Mr. Miller in 1759.

11. Root perennial, long, branching, spreading very far. Stems erect, a yard high and more, alternately branched, leafy, round, smooth, frequently flexuose, panicled at top with numerous branches of small white flowers, in little corymbs. Leaves alternate, acute, broad-lanceolate, lengthened out at the base and tip, serrate in the middle, glaucous especially beneath [1]. Silicle heart-shaped, with a short style and globular stigma. The young leaves are eaten sometimes in salads: they have a pungent acrid taste [2]. This plant is one of the acrid antiscorbutics, and was formerly used in the place of Horse-radish. An infusion of it vomits [3]. Having a hot biting taste like Pepper, and the leaves having been often used by the country people to give a relish to their viands instead of Pepper, it had the appellation of *Poor-man's Pepper*.

[Native of several parts of Europe. In Britain, at Hythe near Colchester, Heybridge near Maldon, in marshes near Grays, and other places in Essex: below Shetingham cliffs in Norfolk: between Beningborough and Mutton in the North Riding of Yorkshire: near Seaton, plentifully: about the castle of Weems, in Fifeshire, &c. It flowers in july.

12. Stem perennial, herbaceous, round, from upright ascending, with panicled branches, from a foot to a yard in height. Leaves scattered, alternate, attenuated at both ends; deeply serrate, spreading, smooth; the upper ones smaller, serrate only at the tip. Petioles shorter by half than the leaves, flat, keeled on the outside. Universal pedunctes terminating, round, even, leafless: racemes simple, during the time of flowering contracted, corymbed, whilst fruiting cylindrical. Pedicels very many, scattered, filiform, round, spreading, half an inch long, one-flowered. Flowers white, two lines in diameter. Silicles ovate-cordate, compressed, with one ovate, acute, reddish yellow seed in each cell.

Native of **New Zealand**, especially at Charlotte Sound.

This plant, with Apium or Smallage and Tetragonia halimifolia, was of considerable service to the ships crews under Captain Cook, when they lay in Charlotte Sound [4].

Introduced in 1779, by Jonas Dryander, M. A.[5]

13. Root perennial, producing a tuft of permanent leaves and branches. Stems scarcely a span high, simple, subtomentose. Leaves linear, acute, flat above, semicylindric beneath. Racemes terminating, and from the axils of the upper leaves, simple. Petals white. Silicle as in L. roderale. Stamens fix.

Native of Spain [6]. Cultivated by Mr. Miller in 1768.

14. Root perennial. Stature of L. sativum. Stems round, smooth and even. First root-leaves pinnate-lyrate; lower stem-leaves serrate, upper linear, quite entire. Flowers small, white. Calyxes tinged with purple. It resembles Iberis graminifolia, but is distinct from it. When adult, it casts the leaves.—Native of the South of Europe [7].

15. Stems upright, filiform, green. Leaves narrow-lanceolate, quite entire, even, thin not fleshy, green, spreading, often several at the buds. Corymbs small, white. Petals scarcely longer than the calyx, distant. Stamens fix, with yellow anthers. Fruit of Nasturtium. It differs from the preceding in being two feet high, with flat leaves; the lower serrate; calyxes red; petals broader, obovate.—Native of Spain [8].

16. Root annual, small, fibrous. Stems procumbent, hairy, alternately branched, leafy. (Linneus says they are a foot long and even.) Leaves alternate, smooth, pinnatifid: the lobes notched especially on the fore side. Spikes generally opposite to the leaves, many-flowered, soon lengthened out into racemes. Flowers very small, with two or four stamens, scarcely more. Silicle very distinctly two-lobed, rugged, very much resembling that of *Cochlearia Coronopus*, to which this plant is very nearly related as to generic character; and indeed Linneus says, it is an intermediate species between the two genera [9].

This plant escaped Ray and Dillenius. Hudson mentions it as a native of Devonshire and Cornwall, among rubbish. About Exeter, Truro and Penryn. At Dale, near the entrance of Milford Haven. It flowers in july.

17. Root annual or biennial. Stem a foot high, usually crooked, woody, stiff, branched. Leaves fleshy, smooth. Peduncles slender. Flowers very small, in clustered spikes or racemes. Calyxes pale yellow. Haller, (in the second edition of Stirp. Helvet.) Gouan and others affirm that there are no petals, and Pollich could never find any. Scopoli on the contrary says that it is not apetalous, and De Necker describes each of the four petals as obovate, clawed, and twice as long as the calyx. The truth seems to be that the petals are more frequently wanting, but that they do exist; and accordingly Haller, in the first edition of his Stirpes Helveticæ describes the flowers as white, though very small. Linneus assigns two stamens only to the flowers, this seems generally to be the case, but there are sometimes four, though Gouan could never discern that number. Scopoli affirms that the flowers are never diandrous in Carniola. Silicles numerous, small, much compressed, containing one seed in each cell. The plant has a pungent taste, and a fetid smell like a fox [10].

Native of most parts of Europe, in waste places, especially near the sea coast. Malden, Essex. Wisbeach, Cambridgeshire. Yarmouth, Lynn, and Clay, Norfolk. By the Severn above Worcester; near King's Weston below Bristol. Truro, Cornwall. Coast of Scotland. It flowers in june and july.

18. Root annual, single, white, an inch long. Root-leaves an inch in length, half of them being foot-stalk, and reddish, with three or four deep jags, at the beginning oval, half an inch broad, indented about the edges, smooth, dark green. Stalk round, whitish green, a foot and half high, having longer, narrower, deeper cut leaves set thick about it without any order; the branches also come out frequently on all sides, and round them many flowers, small, white, four-petalled, on peduncles the eighth part of an inch in length. Silicle round, emarginate, containing one oblong reddish seed in each cell.

Native of all the Caribbee islands [11], and Virginia. Cultivated in Chelsea garden in 1713. It flowers in june and july [12]. In the West Indies the inhabitants eat the leaves in their salads, as we do those of L. sativum or Garden Cress.

[19. Native of the Cape of Good Hope, where it was found by Mr. Francis Masson. Introduced in 1774. It flowers from may to august [13].

20. This has a long fleshy root, which runs deep into the ground, and sends out many oblong leaves spreading flat on the ground. Stalks slender, stiff, branching out horizontally on every side, about two feet high. The flowers come out in small close clusters at the ends of the branches: they are white, and appear in june and july. The seeds ripen in autumn. The plant is recommended as having the same qualities with L. latifolium, and is sometimes called *Sciatica* Cress.

Native of the South of France, Italy, Sicily, [Germany, Spain, Siberia.—Cultivated in 1683 by Mr. James Sutherland [14].]

21. Leaves and stalks much like those of Garden Cress, but more divided, and of a different taste and smell. Petals so small as to be almost imperceptible; and only two stamens to each flower. [Murray affirms that it has six stamens. Dillenius observed only two. The number certainly varies much in this genus. Dillenius describes this plant as two feet high and more, with many branches very full of leaves in bundles, resembling those of Tansey, but less cut, and

[12] Hort. kew. [13] Ibid. [14] Ibid.

having small hairs on the back and along the edges. Flowers in oblong terminating spikes, that lengthen out as the fructification advances. Flowers so small as not to be seen with the naked eye. Petals roundish, white, reflex. Silicles small, compressed, emarginate, with one compressed, yellowish seed in each cell [a].

Native of Buenos Ayres, Brasil and other parts of America. Cultivated before 1732 in the Eltham garden.] Mr. Miller says that the seeds came up in the earth from several parts of America. [It has also been found at the southern end of Africa.]

22. This has creeping roots. Leaves longer and narrower than those of Cochlearia Draba, and less hoary. Flowers in loose bunches at the end of the branches, small and white. [Linneus remarks, that it has the appearance of Thlaspi campestre, insomuch that it can scarcely be distinguished but by the silicles. It is to be removed from Lepidium Draba, which is a *Cochlearia*, the silicles being perfectly those of a Lepidium, and not gibbous at the base as in that.

Native of the Levant, about Aleppo.

23. Stem herbaceous, two feet high, with the branches spreading at bottom and thence ascending, round and even. Leaves alternate, spreading, loose, two inches long, the lower ones of the stem attenuated at the base. Racemes terminating, solitary, simple. Peduncles round, even, almost upright, two hands in length. Pedicels scattered, filiform, spreading, corymbed, even, one-flowered, two lines in length. Flowers small, white. Nectary of six minute, compressed green glands, between the stamens. Silicle oval, compressed, emarginate. Seeds subsolitary.

Native of the islands in the South Sea. Botany island, Teautea and Humheine. It is used by the inhabitants for taking fishes by inebriating them. It is very acrid, and was used by our circumnavigators in their salads with L. oleraceum, which it resembles, but differs in many essential marks [b].

PROPAGATION AND CULTURE.

1. Sow the seeds in autumn, for those which are sown in the spring seldom flower the same year, and are often killed by the frost in winter; whereas those which are sown in the autumn, or the plants that rise from scattered seeds always flower about midsummer, and the seeds ripen in august and september following. The plants require no other care but to thin them, and keep them clean from weeds.

3. If the seeds of this and the other annual sorts be sown in the autumn, the plants will flower in april, may or june, and the seeds will ripen in may, june or july. If these be permitted to scatter, the plants will come up in autumn, and require no other care but to thin them when they are too close, and to weed them.

9. The seeds of common Garden Cress are sown in drills pretty close, in winter on moderate hot-beds, in spring and autumn on borders, and are soon fit for use. It should be cut young, otherwise it will be too rank.

11. This, with the other perennial sorts, is easily propagated, for every piece of the root will grow and multiply wherever it is planted, and will become difficult to root out in a garden, when it is once established.

13. This may be increased by seeds or cuttings. Sow the seeds in the spring on a bed of light earth in the open air, and when the plants are fit to transplant, set a few in pots, that they may be sheltered in winter under a common frame; for in sharp winters those plants which are exposed to the open air are frequently killed. Put the remaining plants in a dry rubbishy ground, in a sheltered situation, where by growing slowly they will become more shrubby, and be in less danger of suffering by cold.

18. Sow the seeds in april upon an open bed where the plants are designed to remain; thin them where they are too close, and keep them clean from weeds. If the seeds be permitted to scatter in the autumn, the plants will come up very well. N. 10. may be propagated in the same way.

20. The roots will abide several years in a dry soil. If the seeds be permitted to scatter, they will come up early in the spring without care.

21. Sow the seeds on a moderate hot-bed in the spring, and when the plants have obtained strength transplant them on a warm border.

22. This is a perennial plant which increases by its creeping roots in great plenty.

DESCRIPTIONS, &c.

1. Bulb oblong, shaped like that of the Daffodil, but smaller. Leaves flat, deep green, four or five in number, broader and longer than those of the common Snow-drop (Galanthus nivalis). Scape angular, near a foot high, hollow and channelled: towards the top comes out a whitish sheath, opening on the side, out of which come two or three flowers, hanging on slender pedunicles. Corolla much larger than that of the common Snow-drop; and the ends of the petals are green. They appear in march, and have an agreeable scent, not much unlike those of the Hawthorn. [In its wild state, the scape is only half a foot in height or little more, and generally has only one flower, very seldom two. The capsule is obscurely and bluntly three-cornered. The three inner petals are narrower and a little shorter. The whole plant is very smooth[a].

The flowers, which at first sight resemble those of the common Snow-drop, are easily distinguished by the absence of the three-leaved nectary. They do not come out so soon by a month. This plant, being of a different genus from the true Snow-drop, ought certainly to have another English name; Mr. Curtis therefore calls it *Spring Snow-Flake*[b]. Parkinson had named it *Great early bulbous Violet*, and Gerarde *Late-flowering bulbous Violet*.

Native of Italy, the South of France, Germany, Austria, Switzerland.—Cultivated in 1596 by Gerarde[c].

2. Bulb the size of a Chestnut, somewhat ovate, outwardly pale brown, inwardly white; coats numerous, thin and closely compacted.] Mr. Miller says, the bulb is nearly as large as that of the common Daffodil, and very like it in shape: that the leaves also are not unlike those of the Daffodil, more in number than in the preceding, and keeled at the bottom, where they fold over each other, and embrace the stalk. [Leaves about a foot and half in length, upright, nearly linear, almost an inch in breadth, obtuse, the lower ones shortest. Scape a little higher than the leaves, hollow, slightly flatted, two-edged, a little twisted, one side sometimes obtuse, the other acute. Peduncles for the most part five from the same sheath, each supporting a single flower, angular, and of unequal lengths. Flowers pendulous, growing all one way, having little scent. Petals white, finely grooved within, not at all uniting at bottom; the tips thickish, a little puckered, and marked with a green spot. Seeds large, black and glossy[d].] The flowers appear at the end of april or the beginning of may, and there is a succession of them during three weeks, or longer in cool weather.

[Native of Hungary, Austria, Carniola, Tuscany, Silesia. Mr. Curtis first observed it in England between Greenwich and Woolwich, about half a mile below the former place, close by the Thames side, just above high water mark, with Reed, Marsh Marigold, and other common water plants, and in a similar situation to that in which it is found wild in Austria. It has also been found wild in the Isle of Dogs, which is the opposite shore. It grows here even more luxuriantly than in gardens, where it seldom has a soil or situation sufficiently moist.—Mr. Gough found it in a small island, in the river, about three miles S. of Kendal, on the dam of the gunpowder mill.

Mr. Curtis, to distinguish it from Galanthus, names it *Summer Snow-Flake*. Parkinson calls it *Great late-flowering Bulbous Violet*: Gerarde, *Great many-flowered Bulbous Violet*. In the gardens it is known by the name of *Great Summer Snow-drop*; *late* or *tall Snow-drop*.

3. Bulb thick for the size of the plant, composed of many glutinous coats, bitter, covered with a whitish membrane. Scape slender, brownish, a hand in height, supporting two or three small white flowers (sometimes only one), hanging down, having no smell. It is distinguished by its four or five capillary leaves[e]; which begin to spring up after the flower is past, when the seeds are ripening, and sometimes after the heads are ripe. They abide all the winter and spring following, and wither away in the beginning of summer; leaving the scape to appear naked. The flowers are a little reddish at the bottom next the stalk[f].

Native of Portugal, and Spain on the confines near Badajos.—Introduced in 1765, by Mr. Joshua Brooks. It flowers in september[g].

4. Bulb roundish, white, less than a hazel nut. Leaves two or three, inclosed at the base in a white sheath, filiform, dotted with white, keeled at bottom, flat, or a little convex on the back, weak and more or less lying on the ground. Scape flexuose-erect, slender, about half a foot high, roundish, terminated by a spreading umbel of from three to seven flowers. Valves of the spathe lanceolate, acute, membranaceous, opposite, sometimes equal sometimes not, pale. Peduncles filiform, one-flowered, unequal, from one to two inches in length. Flowers without scent, coming out successively. Petals white within, purplish without, oblong-lanceolate, three lines in length; the three inner bluntish: the three outer acute, with a blunt, greenish keel. Anthers purple. Germ three-cornered, green. Style white, swelled out at bottom into a body larger than the germ, plaited at bottom; thence awl-shaped, bluntly three-cornered, the length of the stamens.

[a] Jacquin. [b] Magaz. [c] Hort. kew. [d] Curtis. [e] Clusius. [f] Parkinson. [g] Hort. kew.

Stigma

Stigma obſcurely trifid. Capſule ſubglobular, three-cornered, or rather compoſed of three. The whole plant is ſmooth [1]. See *Crinum teneſſum.*

Native of the Cape of Good Hope, where it was diſcovered by Maſſon. Introduced in 1774. It flowers in november [2].]

PROPAGATION AND CULTURE.

Theſe bulbs are increaſed by offſets, which the two firſt ſorts put out pretty plentifully, in a favourable ſituation, when they are not too often removed. They ſhould have a ſoft loamy ſoil, and an expoſure to the eaſt. Plant the roots ſix inches aſunder, and four or five inches deep. They ſhould not be tranſplanted oftener than every third year.

[A north or north-eaſt border is beſt for them; and the proper ſoil a mixture of loam and bog earth. In different aſpects however their flowering may be forwarded or protracted, and thus a longer ſucceſſion of theſe and other flowers produced [3].

The fourth ſort muſt be houſed with other Cape Bulbs, and treated as they are.

   Leaves linear three-ſided, calyx rayed, all the leaflets coloured.

DESCRIPTIONS, &c.

1. Leaves imbricated in five, not four, rows. Calyx five-parted. Petals five, linear, having a chink on each ſide of the claw with a converging margin. Stamens filiform, long. Germ ſuperior, two-celled. Styles two, approximating [4]. Linnæus himſelf remarks, that this ſpecies is ſufficiently diſtinct from the other Brunias, by its having two ſtyles, and a ſuperior two-celled fruit. Gaertner indeed affirms, that the fruit is half inferior, but in this he is probably miſtaken. He thinks it is rather a nut than a drupa. He deſcribes it however as a juiceleſs drupa, corticated by the calyx growing very cloſely to it, ſmall, ovate, woolly: rind membranaceous, thin: ſhell hard, ſomewhat bony, two-celled, valveleſs. Receptacle double: of the fruit globular, chaffy, villoſe: of the ſeed ovate-globular, fungoſe, very large, receiving on each ſide a very thin partition, faſtened to it. Seeds five or ſix in each cell, ſmall, ovate-oblong, narrower at top, compreſſed, pale, ruſeſcent, pendulous; with a terminating ſublateral umbilicus.

Introduced in 1786, by Mr. Francis Maſſon [5].

2. This ſhrub reſembles the preceding, but it has ſmaller leaves, covering the branches. Heads or flowers many, panicled. Chaffs between the florets ſtanding out twice their length, pale, longer than the calycine leaflets. Styles two. Receptacle hairy [6].

3. Leaves bluntiſh, with a brown callority at the tip, flat above, keeled underneath, ſmooth, about two lines in length, petioled, ſcattered, approximating, on the young ſhoots hairy. Petioles broad, ſhort, from upright preſſed cloſe. Heads of flowers globular, terminating, ſubumbelled; on round peduncles, covered with ſmall, ſubimbricate, leafy ſcales, one-flowered, ſomewhat villoſe, gibboſe and ſucculent at bottom. Corolla white [7]. Germ ſuperior. Style one, emarginate [8].

Introduced in 1787, by Mr. Francis Maſſon [9].

4. Stem from a foot to two feet in height, the ſize of a ſwan's quill, upright, round, leafy, ſcarred, determinately branched, dichotomous or trichotomous; the branches rod-like, hairy. Leaves ſcattered, approximating, from upright ſpreading, petioled, acute, dark green with brown tips, having a few hairs, when more advanced naked, channelled, permanent. Petioles linear, very ſhort, erect. Hairs ſimple. Common perianth the ſize of a Pepper-corn, with blunt leaflets, hairy at the baſe; the outer ones ſhorter, rude; the inner whitiſh, the length of the diſk, ſpreading, reſembling a ray. Common corolla duſky, not at all glutinous. Receptacle hairy [10].

Introduced in 1787, by Mr. Francis Maſſon [11].

5. Stem from a foot to two feet in height, the ſize of a ſwan's quill, upright, round, grooved, ſcarred, very much branched; branches proliferous, upright, hairy. Leaves ſcattered, approximating, from upright

ſpreading, petioled, blunt, dark green with a brown callous dot at the tip; the younger ones having frequently a few hairs; when farther advanced naked, channelled, permanent. Petioles linear, very ſhort, upright. Hairs ſimple. Common perianth the ſize of a Pea, with the leaflets biglandular at the baſe, longer than the diſk, whitiſh, ſpreading, reſembling a ray. Common corolla duſky, very glutinous. Receptacle chaffy. This differs from the preceding, which it reſembles very much, in a proliferous ſtem, the leaflets of the common perianth all coloured, and longer than the diſk, the corolla glutinous, and the receptacle chaffy [1].

Theſe are all ſhrubs, and natives of the Cape of Good Hope.

Relhania paleacea. *L'Herit. ſert.* 24.
Leaves three-ſided callous at the tip and curved back.

DESCRIPTIONS, &c.

1. This is an evergreen ſhrub, with a balſamic ſmell. The trunk and older branches leafleſs, brown; the younger ones very cloſely covered with leaves, and ſpreading out very wide. Leaves very much cluſtered, filiform, ſpreading, quite entire, hoary, woolly, flaccid, an inch long, with brown-headed hairs. Among theſe are bundles of very ſmall leaves, like the rudiments of young branches, very few however of which come to perfection. Peduncles filiform at the ends of the branchlets, ſolitary one-flowered. Calycine ſcales pale, with the middle of the back green. Corolla yellow. Seeds browniſh [2].

Native of the Cape of Good Hope. Introduced in 1774, by Mr. Francis Maſſon. It flowers from July to ſeptember [3].

2. Receptacle flat, with raiſed dots in the middle, naked, rugged, and having a ſingle row of chaffs in the circumference: chaffs ſcarioſe, white, covering the germs of the females externally, and ſcarcely or but little longer. Seeds uniform, linear-oblong, compreſſed, ſomewhat rugged at the edges and ferruginous. Pappus or down difform; in the ray ſimple, chaffy, ten-leaved; leaflets linear-acuminate, white, one-fourth of the length of the ſeed: in the diſk compoſed of five rays, which are chaffy, linear-acuminate, very ſhort; and of five others which are feathery, longer than the ſeed, and alternate with the others. Sometimes a ſingle feathered ray is added to the down of the females; and in the ſeeds of the androgynous flowers the chaffy rays are frequently augmented by a leaflet or two, ſo that from five-leaved they become from ſix to eight-leaved [4].

Native of the Cape of Good Hope.

3. Leaves with few hairs on them, with a tomentoſe groove on the inſide. The whole receptacle covered with chaffs almoſt the length of the flowers. The whole crown of the ſeed membranaceous, and none downy. Hence it agrees in character with Buphthalmum, but it reſembles the preceding ſo much, as ſcarcely to be diſtinguiſhed from it in appearance [5]. L'Heritier removes it into a new genus to which he has given the name of *Relhania*.

Gærtner deſcribes the receptacle as flattiſh, narrow, chaffy: chaffs the length of the florets, linear, very narrow, deciduous. Seeds uniform, oblong, narrowing downwards, obſcurely angular or almoſt cylindrical, ſmooth, bay-coloured. Pappus or down one-leafed, tubular, ſcarioſe, white, little leſs than a third part of the ſeed in length: the aperture of the tube in the ſeeds of the ray quite entire; in the others obſcurely and bluntly four-toothed. He refers the ſpecies with a naked receptacle and a compound down to Vaillant's genus of *Aſteropterus*.

Native of the Cape of Good Hope.

Leaves linear ciliate at the baſe, flowers in ſpikes ſeſſile lateral, ſtem ſimple.

DESCRIPTION, *&c.*

This genus conſiſts of ſpecies ſeparated from Serratula, on account of the down being feathered and the receptacle naked. Juſſieu ſaw the neceſſity of this, and was of opinion that theſe plants are nearer to Eupatorium or Cacalia. Gærtner ſeeing that they are diſtinct both from Serratula and Eupatorium gave them the name of *Suprago*. Walter ſaw that they were diſtinct, but did not give them a generic name.

1. Stems ſeveral, ten or twelve feet high, ſmooth, deeply ſtriated, pale green, ſtout, rigid, ſtraight, not branching except at top for the flowers. Leaves alternate, very long, narrow in proportion to their length, veined, wrinkled, roughiſh but without hairs, dark green above, ſomewhat hoary underneath. Flowers in a ſort of umbel (or corymb) at top, conſiſting of fewer heads than in L. glauca, leſs ſcattered, and ſmall in proportion to the plant. Heads more ſtrigoſe, the florets not turned ſo much outwards: calycine ſcales, eſpecially the lower narrower, and ending in ſlender oblong horns. It ſeldom flowers till the end of october. The florets are of a deep purple colour, and the calyx is ringed with purple. Seeds oblong, columnar, whitiſh: crowned with a hairy, ſtiffiſh, browniſh down. Receptacle naked.

Native not only of New York, but of Virginia, Carolina, and other parts of North America [a]. Cultivated in 1732, by James Sherard, M.D.[b]

2. Root perennial, large, ſtriking deep into the ground. Stems branching only at top, ſeven or eight feet high, purpliſh, ſtraight, deeply ſtriated. Leaves ſeven inches long, and an inch and half broad in the middle, ending in acute points, entire, deep green above, hoary on their under ſide, ſeſſile. Flowers in looſe erect bunches at the ends of the branches. Calyxes oval, compoſed of few ſcales terminating in brittles. Florets pale purple.

[Dillenius obſerves, that the leaves are ſhorter and leſs wrinkled, wider in the middle, not pendulous, as in the preceding, but either horizontal or pointing obliquely upwards; they are alſo leſs ſerrate and more minutely, yelloviſh green above, and more hoary beneath. In figure and toothing they are like Peach leaves, but differ from them in being wrinkled above and hoary beneath. The heads of flowers are ſomewhat rounder, and the cuſps or horns at the end of the calycine ſcales are ſhorter. Receptacle naked.

Native of Virginia and Carolina [c], and other parts of North America. Cultivated in 1732, by James Sherard, M.D. It flowers from ſeptember to november [d].]

3. Root perennial. Stems ſix or ſeven feet high, purple and channelled. Leaves three inches long, and an inch and half broad in the middle, ſtiff, and light green on both ſides.

[Stems ſtraight, ſmooth, unbranched except at top, where the flowering branches are a foot or eighteen inches in length, divided and ſubdivided into many others. Calyxes very dark purple. Down very prominent, of a pale or whitiſh brown. Florets dark purple, inclining to violet. The leaves are ſmooth, dark glaucous green above, paler glaucous beneath, woolly along the veins and nerves [e]. Receptacle flat, naked, obſcurely excavated, ſmooth. Seeds oblong, quadrangularly columnar, ſtriated, ſmooth, rufeſcent-bay-coloured. Down ſetaceous, thiffiſh, ſomewhat brittle, dirty white, tooth-ciliate; the outmoſt rays very ſhort, the reſt longer than the ſeed [f].

Native of Maryland, Virginia, and Carolina. Cultivated in 1732, by James Sherard, M.D. at Eltham.

4. Root tuberous. Root-leaves a foot long, and half an inch wide, rigid and nerved. Stems ſeveral, ſimple, from two to three feet in height, the thickneſs of the little finger, covered with a fine pubeſcence, and having many alternate leaves, reflex, rigid, nerved, with ſtraight veins, ſubhirſute, like thoſe of Tragopogon but not ending in ſo acute a point, not embracing the ſtem, all ſhorter than the root-leaves, gradually ſmaller and narrower towards the top of the ſtem, ſmooth above, hairy beneath and along the edges. Peduncles an inch long, alternate from the upper axils. Heads of flowers ſquarroſe, with leafy ſcales ſtanding out and bent back, keeled, ſubhirſute; with the florets turned outwards, from the middle of which very long two-parted ſtyles hang out, making them appear as it were bearded. Each floret is long, horn-ſhaped, and curved inwards; ſegments narrow, villoſe within, ſmooth without, purple. Seeds oblong, ſtriated, crowned with a feathered down. Receptacle naked.

Native of moſt of the provinces in North America [g].] Mr. Miller ſays that he received the ſeeds from Carolina. [The Kew catalogue aſſigns it to Virginia. In 1732 it was cultivated in the Eltham garden. It flowers in july and auguſt.

5. This differs very much from the preceding. The calyxes are ſquarroſe and blunt; the peduncles lateral, elongated, one-flowered, with a few leaflets; the leaves broad-lanceolate, not at all nerved, ſeſſile but not decurrent [h].]

Root large, tuberous. Stem one, ſtrong, channelled, three or four feet high. Leaves three inches long, and half an inch broad. Flowers purple, in a

[a] Dillenius. [b] Hort. kew. [c] Dillen. elth. [d] Hort. kew. [e] Dillenius. [f] Gærtner. [g] Dillenius. [h] Linn. ſpec.

long,

long, loose spike, at the upper part of the stem, on pretty long blunt peduncles, they have large rough calyxes, composed of wedge-shaped scales. The flowers at the top of the spike open first. It flowers in august, but the seeds do not ripen here.

Native of Virginia. Cultivated by Mr. Miller in 1759[1].

6. Stem hairy, from three to five feet in height. Flowers purple, sessile, subimbricate, in spikes. Calyxes many-flowered with the scales pressed close. Stems simple. If this be Anonymos pilosus of Walter.

Native of North America. Introduced in 1783 by Mr. William Young. It flowers in september and october[2].

7. Stem upright, two feet high, tomentose. Calyxes five-flowered, red at the tip[3].

Native of Carolina and Georgia. Introduced in 1787, by Messrs. Watsons. It flowers in october[4].

8. Root tuberous. Stem smooth, three feet high. Flowers purple, subimbricate, on short peduncles. Calyxes many-flowered, with the scales less obtuse and less converging[5].

Calyx subcylindric, imbricate, with oblong blunt scales, pressed close, glutinous as is the whole plant. Receptacle narrow, scrobiculate, smooth. Florets red, with the styles deeply bifid, and the stigmas filiform and very long. Seeds oblong, acuminate downwards, triangular or rhomb-compressed, striated, smooth, lead-bay-colour. Down the length of the seed, whitish, with numerous, equal, setaceous, tooth-ciliate rays[6].

Native of North America; where it is called *Throat-wort*, the root being discutient[7]. Cultivated in 1732, by James Sherard, M. D. It flowers from august to october[8].

Walter has five species besides the two mentioned above.

1. Anonymos graminifolius, n. 3. with a simple smooth stem, six feet high. Leaves long, like those of grass, subvillose within. Flowers purple, sessile, in spikes. Calyxes many-flowered, with blunt subconverging scales.

2. Anonymos ramosus, n. 4. Stem somewhat branched, four feet high, pubescent. Leaves lanceolate. Flowers subsessile, purple, in spikes. Calyxes many-flowered, with blunt subconverging scales.

3. Anonymos paniculatus, n. 5. Stem hairy, viscid, a foot high, simple. Leaves lanceolate, ascending, hairy. Panicle terminating. Calyxes simple, five-leaved, five-flowered. It varies with purple and with white flowers.

4. Anonymos uniflorus, n. 6. Stem short, branched. Leaves lanceolate. Flowers terminating. Peduncles one-flowered. Calyxes many-flowered with converging scales.

5. Anonymos odoratissimus, n. 7. Stem three or four feet high. Root-leaves obovate-oblong. Stem-leaves oblong-lanceolate, even. Flowers in corymbs, purple.

Gmelin has inserted these species among the Chrysocomas, as it should seem without any foundation.

Claſſ. 24. 5. Cryptogamia Algæ.

Nat. order of *Algæ.*

GENERIC CHARACTER.

* *Male* flowers?

Veſicles conglomerated, extremely small, crowded or scattered on the disk, margin, or tips of the fronds.

* *Female* flowers? on the same, or on a distinct plant.

Receptacle roundish, flattish, convex (*Tubercle*), concave (*Scutella*), subrevolute affixed to the margin (*Pelta*), often differing from the frond in colour, within containing the seeds disposed in rows.

Obs. *The powder adhering to some Lichens seems rather to be of the nature of buds than of male fructifications.*

The extremely numerous species of this genus may be conveniently divided into the following sections, some of which by some authors are made distinct genera.

Lepra. Hall. a dusty crust, fructifications hardly any.

Tuberularia. Herpes. Hall. Verrucaria. Wigg. Hoffm. a leafless crust. The fructifications Tubercles.

Scutellularia. Patellaria. Hoffm. a leafless crust. Fr. Scutellæ or shields.

Collema. Hill. Nostoch. Hall. Fronds foliaceous, gelatinous. Frs. Scutellæ or shields.

Imbricaria. Squamaria. Hoffm. Fronds subfoliaceous, membranaceous, imbricated, depressed, flexile Fr. Scutellæ.

Physcia. Fronds foliaceous, membranaceous, depressed, or ascendent, tubular within. Fr. Scutellæ, sessile or pedunculated.

Lobaria. Pulmonarius. Hall. Fronds foliaceous, membranaceous, ascending, flexile. Fr. Scutellæ, sessile or pedunculated.

Cornicularia. Corniculatus. Hall. Fronds foliaceous, membranaceous, or cartilaginous, somewhat upright, narrowed, stiff, with somewhat sharp extremities. Fr. Scutellæ, sometimes terminal, transverse.

Stilta. Fronds foliaceous, subcoriaceous, scattered over beneath with white excavated points. Fr. Scutellæ, or Peltæ.

Peltigera. Wild. Antilyssus. Hall. Fronds foliaceous, coriaceous, ascending, soft. Fr. Peltæ.

Umbilicaria. Hoffm. Fronds foliaceous, upright, stiff, shielded. Fr. Scutellæ.

Pyxidium. Hill. Coralloides. Dillen. Stems upright, somewhat columnar, branchy, hollow within, with the appearance of a shrub; the axillæ often perforated. Fr. fungiform Tubercles.

Stereocaulon. Stems erect, rather columnar, simple or branchy, solid. Fr. Tubercles.

Usnea, Dill. Stems erect, or pendulous, filamentous, simple or branched. Fr. Scutellæ.

Of this very numerous genus Dr. Withering, in the third edition of his arrangements, has enumerated no fewer than 226 species, besides a great number of varieties. Most of these Mosses or rather Algæ are figured by Dillenius, Micheli, Hoffmann, Jacquin, Dickson, Withering, in Flora Danica, English Botany, or the Linnæan Transactions, &c.

Many of them are of considerable use, particularly in dyeing.

Lichen calcareus, so called because it is peculiar to Limestone rocks, when dried, powdered, and steeped in urine, is used to dye scarlet, by the Welch and the inhabitants of the Orkneys. The colour is said to be very fine.

L. Parellus. Litmus is prepared from this species. For this purpose it is gathered from the rocks in the north of England, and sent to London in casks[9].

L. tartareus. Common on limestone rocks in the north of England and in Scotland. It may be known by its peculiar pungent alkaline smell when moistened. It is gathered for the dyers by peasants, who can collect from twenty to thirty pounds a day, and sell it for a penny a pound. They choose such specimens as are of a firm dense texture, and never scrape the same rock oftener than once in five years. It is prepared for use with volatile alkali and alum, but the exact process is kept a secret by the manufacturers at Glasgow. When sold to the dyers, it appears in the form of a purple powder, called *Cudbear*, a corruption of Cuthbert, the name of the inventor. This powder being boiled with woollen yarn, communicates a purple colour to it; but not to vegetable substances. The colour is far from permanent.

[1] Hort. kew. [2] Ibid. [3] Walter. [4] Hort. kew. [5] Walter. [6] Gærtn. [7] Gron. virg. Hort. kew. [8] Withering.

L. Roccella or Orchall as an article of commerce is of very great importance, being extremely valuable for dyeing wool or ſilk any ſhade of purple or crimſon. For this purpoſe it is ſteeped in volatile alkali, commonly diſtilled from urine. In times of ſcarcity, it has been ſold at a thouſand pounds ſterling the ton. It comes chiefly from the Levant; and has lately been diſcovered to grow in the Britiſh dominions [a].

L. omphalodes dyes wool of a brown reddiſh colour, or a dull but durable crimſon, paler but more laſting than that of Orchall. It is prepared by the country people in Ireland by ſteeping it in ſtale urine, adding a little ſalt to it, and making it up into balls with lime. Wool dyed with it, and then dipped in the blue vat, becomes of a beautiful purple. With rotten oak it makes a good dark brown frize. Wool dyed with red wood or ſanders, and afterwards in this, which is called Cork, Corker or Arcell, becomes of a dark reddiſh brown. It has been uſed as a ſtyptic [b]; as has alſo L. plicatus; but theſe have long ſince given way to more active medicines [c].

L. rangiferinus, is well known to be the chief food of the Rein Deer, which will grow fat upon it; and this animal ſupplies every neceſſary of life for the contented Laplander; as is ſet forth at large by Linnæus, in his elegant Flora Lapponica.

L. vulpinus. In Norway they mix this ſpecies with powdered glaſs, and ſtrew it upon dead carcaſes to poiſon wolves. It dyes wool yellow.

L. prunaſtri has a remarkable property of imbibing and retaining odours, and is therefore the baſis of many perfumed powders.

L. iſlandicus. The Icelanders boil this in broth, or dry it and make it into bread. They likewiſe make gruel with it to mix with milk; but the firſt decoction is always thrown away, for it is apt to purge. It has lately got a reputation for curing conſumptive complaints. For which L. pulmonarius has been long in reputation; with more reaſon, I ſhould hope, than L. caninus for the cure of Hydrophobia.

L. pulmonarius dyes woollen cloth of a durable orange. In Herefordſhire they dye ſtockings with it of a durable brown.

L. caperatus. In the north of Ireland and in the Iſle of Man they dye wool with this of an orange colour. Serge dyed with it became of a lemon colour, but if previouſly infuſed and boiled in urine, of a ruſſet brown. It is probably what the people in the north of Ireland call *Stone-crottles*. It is alſo called *Arcell*, from its being put to the ſame uſe with Orchall.

L. puſtulatus. Linnæus ſays that a beautiful red colour may be prepared from this. It may be converted into an exceedingly black paint.

L. apthoſus. The country people make an infuſion of it in milk, and give it to children who have the thruſh. In large doſes it operates by purging and vomiting, and deſtroys worms [d].

Doubtleſs if more accurate and extenſive trials were made on theſe neglected plants, many other oeconomical uſes for them might be detected; or at leaſt many more of the ſpecies might be applied to the ſame purpoſes.

1. Licuala ſpinoſa.

Thunb. act. holm. 1782. *p.* 284. *nov. gen.* 70. *Act. batav.* 2. 469. *Gærtn. fruct.* 2. 268.

Licuala arbor. *Rumph. amb.* 1. 44. *t.* 9.

Corypha foliis palmatis. *Burm. ad Rumph.*

DESCRIPTION, *&c.*

Trunk an ell in height, ſcarcely ſo thick as the human arm, jointed, dividing at top into about ſix branches, each ſix ells long, hardly a finger in thickneſs, triangular, grooved above, flat beneath, the lower half ſharply ſerrate at the angles, and the teeth or ſpinules cloſely joined. Each of theſe has a leaf at top, ſpreading like a fan, and divided into rays, all ſeparated to the baſe: the lateral ones (fourteen) are narrow, blunt and jagged at the end, with four ſtrong nerves meeting at bottom: the middle ray is twenty-four or even twenty-ſeven inches long, and a foot wide at top; it has thirteen or fourteen ribs, alternately prominent on the upper and lower ſide, ſo that it may be folded up, like a fan. When the plant is mature, the flower-ſtalk emerges from the middle, as long as the branches or leaf-ſtalks, involved in ſheaths at the bottom, dividing into five ſmaller flower-ſtalks at top, about a hand in length, bearing green heads in three rows expanding into flowers [e].

There is no common ſpathe, and the partial ſpathes are wandering. Spadix branched. The fruit is a fleſhy, ſmall, oval drupe, retaining the calyx at ſome little diſtance: rind membranaceous, very thin, blackiſh brown; fleſh very little, pulpy, fugacious: ſhell bony, thin, brittle, whitiſh, elliptic-globular, finiſhing at top in a very ſharp ſhort dagger-point: it is alſo pointed at bottom, and ſtriated with a few bony nerves ſomewhat branching; within it is very ſmooth and one-celled. Rumphius compares the fruit with thoſe of the Bay for ſize and figure, except that it is rounder; he adds, that it continues long green, but finally turns brown or blackiſh. Seed elliptic, aſh-coloured, moderately convex on one ſide, and towards the baſe keeled with a very blunt angle in which the umbilical chord is immerſed; on the other ſide gibbous, and marked in the middle with a large teat covering the embryo, which is placed in the middle of the back [f].

Rumphius ſays, that the nut is oblong, very hard, and ſtriated longitudinally.

Native of Macaſſar and Celebes: where they make much uſe of the narrow leaves for tobacco pipes, and of the middle broad one for wrapping up fruit, &c. The wood is of little uſe, being not durable.

LIDBECKIA. See *Catula. Lancifia.* Gærtn, &c. *Cenia.* Juſſ.

LIGHTFOOTIA. (*So named by Swartz in honour of the Reverend John Lightfoot, M.A. author of* Flora Scotica.)

Lin. gen. n. 1609. *Swartz prodr.* 83.

Claſſ. 23. 2. Polygamia Dioecia.

GENERIC CHARACTER.

* *Hermaphrodite.*

CAL. *Perianth* four-leaved: *leaflets* ovate, concave, expanding.

COR. none.

STAM. *Filaments* numerous, filiform, ſeated on the receptacle, permanent. *Anthers* roundiſh.

PIST. *Germ* roundiſh. *Style* none. *Stigma* ſeſſile, ſomewhat headed, furrowed.

PER. *Berry* ovate, umbilicated, one-celled.

SEEDS from three to ſix, oblong, compreſſed, cornered, gloſſy.

[a] Engl. bot. [b] Withering. [c] Engl. bot. [d] Withering. [e] Rumphius. [f] Gærtner.

* *Males* on different individuals.

CAL. *Perianth* four-leaved: *leaflets* oblong, concave, equal, coloured.
COR. none.
STAM. *Filaments* numerous, (twenty-four), filiform, longer than the calyx, inserted into the receptacle. *Authers* roundish.
PIST. none.

Females on different individuals.

CAL. as in the male, but larger.
COR. none.
PIST. *Germ* oblong. *Style* none. *Stigma* elevated, quadrangular-headed, furrowed, with convoluted margins; permanent.
PER. *Berry oblong*, seated on a very small receptacle, umbilicated, one-celled.
SEEDS three, five, to six, as above.
OBS. *This genus is allied to* Prockia. *Sw.*

ESSENTIAL CHARACTER.

Cal. four-leaved. *Cor.* none. FEM. and FERM. *Stigma* sessile. *Berry* umbilicated, one-celled, with from three to six seeds.

SPECIES.

1. Lightfootia ferrara.
Swartz prodr. 83. *Vahl symb.* 3. 69.
Leaves oblong-ovate serrate acuminate, pedunckes lateral aggregate one-flowered.
2. Lightfootia theæformis.
Vahl symb. 3. 69.
Leaves lanceolate-elliptic serrate bluntish, pedunckes axillary subsolitary one-flowered.
3. Lightfootia integrifolia.
Vahl symb. 3. 70.
Leaves subcoriaceous oblong and obovate emarginate almost quite entire, pedunckes lateral subaggregate, one-flowered.

DESCRIPTIONS, *&c.*

1. Native of Montserrat.

2. This has the habit of the Tea shrub. Branches, and all the other parts smooth. Leaves petioled, alternate, two inches long and more, nerved and veined, sometimes emarginate, a little bent at the base to the petiole; which is very short, and a little edged by the leaf running down it. Pedunckes one or two, placed on a tubercle, an inch and half long, with a small scale towards the base. Calyx thin, membranaceous. Germ conical. Stigma sessile, flattish. Berry oblong, one-celled. Seeds three or four, smooth, shining. Native of the isle of Bourbon.

3. This is also a shrub, with round smooth branches, covered with an ash-coloured bark. Leaves petioled, an inch and more in length, alternate, sometimes but rarely obovate, scarce simply veined, acute at the base, subcoriaceous, obscurely crenulate, even. Pedunckes three to six, from the axils or at the sides of the branches, short, with a few scales on them. Flowers larger than in the other sorts. Calycine leaflets blunt. Stigma as in the preceding.

These agree with Prockia in calyx, stamens and habit, but differ in the stigma. Hermaphrodite flowers only having hitherto been observed, we are not certain that these two species are polygamous.

Gmelin has erred in referring Lightfootia oxycoccoides and subulata of L'Heritier to this genus; for they have nothing in common with Lightfootia of Swartz*.

DESCRIPTIONS, *&c.*

1. Root ſtrong, fleſhy, perennial, ſtriking deep into the ground, and compoſed of many ſtrong fleſhy fibres covered with a brown ſkin, and having a ſtrong hot aromatic ſmell and taſte. Leaves large, compoſed of many leaflets ſhaped like thoſe of Smallage, but larger and of a deeper green. Stems ſix or ſeven feet high, large and channelled, dividing into ſeveral branches, each terminated by a large umbel of yellow flowers.

[General involucre ſeven-leaved, with the leaflets frequently confluent and bent back. Partial involucre one-leafed, cloven into ſeven or more parts, bent back, the ſegments augmented by a white membrane. Petals very ſmall, yelloviſh green with a yellow receptacle [a]. Fruit ovate-oblong, crowned with an obſcure rudiment of the calyx, emarginate at top and bottom, winged. Seeds of the ſame form, convex on one ſide, with three narrow approximating wings, and ſurrounded with a broader ridged not flexile margin, flat on the other ſide and marked with a raiſed longitudinal line, whiſh bay-coloured [b].

Native of the Alps of Italy, the South of France, Sileſia, &c. Cultivated in 1596, by Gerarde [c]. It flowers in June and July, and the ſeeds ripen in autumn.

[The odour of this plant is very ſtrong and peculiarly ungrateful; its taſte is warm and aromatic. It abounds with a yelloviſh gummy-reſinous juice, very much reſembling Opoponax. Its qualities are ſuppoſed to be ſimilar to thoſe of Angelica and Maſterwort in expelling flatulencies, exciting ſweat, and opening obſtructions: therefore chiefly uſed in hyſterical diſorders, and in uterine obſtructions. A tea cup full of the juice with rheniſh wine, or a decoction of the ſeeds with wine or mugwort water was by Foreſtus ſaid to be a ſecret remedy of extraordinary efficacy in ſlow or laborious parturition. The leaves, eaten as ſalad are accounted as emmenagogue. The root, which is leſs ungrateful than the leaves, is ſaid to poſſeſs ſimilar virtues, and may be employed in powder [d].]

2. This has a biennial root, (all other authors ſay, perennial) of much leſs ſize than the preceding; the leaflets are broader and ſhorter; each leaf having two or three ternate leaflets, indented on their edges. The ſtalk riſes about a foot high, and ſuſtains a ſmall umbel of yellow flowers, ſhaped like thoſe of the preceding.

[Linnæus remarks that the leaves are lucid or gloſſy underneath. The leaflets are oblong-wedge-ſhaped, entire below, above irregularly ſerrate, and ſometimes deeply cut [e].

Native of North America, Sweden, Denmark, Scotland, on rocks near the coaſt. It is much valued in the iſle of Sky. The root is reckoned a good carminative; and an infuſion of the leaves in whey, a good purge for calves. It is alſo uſed for food, either as a ſalad, or boiled as greens [f].]

3. Root thick, fleſhy, like that of Parſnep, ſtriking deep into the ground. Leaves large, deep green, when bruiſed emitting a fetid odour; the leaflets are cut into acute points. Stems three or four feet high, large and hollow, ſuſtaining large umbels of yelloviſh flowers.

[Terminating umbel fertile, lateral ones male [g]. Seeds, when ripe, curved inwards, yellow-ruſt-colour, on one ſide deeply grooved, and having three rigid ribs winging, on the other having a longitudinal groove and two very narrow reflex wings. Albumen oblong, ſtrong-ſmelling, with two depreſſed grooves on the back, and one on the belly. Embryo very ſhort, ovate-globular, milky [h].

Native of Switzerland, Auſtria, Dauphiné, Sileſia, Italy, Peloponneſus, Siberia. Cultivated in 1516, by Gerarde [i].

4. Root half a foot long or more, the thickneſs of the human thumb, often branched, yelloviſh brown on the outſide, pale within and ſpongy. Stem upright, from two to three feet in height, grooved, hollow without any partitions at the joints, the whole leafy, as thick as the thumb or finger, ſimply branched at top only. Root-leaves very large; ſtem-leaves above the middle ſeſſile. Leaflets of the general involucre lanceolate, acute, pale green with a whitiſh membranaceous edge, about half the length of the umbel, reflex, entire or variouſly gaſhed; of the partial involucre about ſix, all commonly quite entire, the outer equalling the umbellets, and not bent back. Terminating umbel of about forty rays, from four to ſeven inches in diameter. The reſt much ſmaller, all cloſe. Theſe, which are at the tops of the branches, flower later, and gradually exceed the primary umbel in height, ſurrounding it when in fruit. Flowers ſtrong-ſmelling, large, all fertile. Petals white, ſubovate, blunt iſh, a little concave, ſpreading very much, not inflex-cordate. Fruit ovate, acute. Seeds ovate, browniſh or pale, flat on one ſide, on the other convex and deeply four-grooved. The whole plant is ſmooth [k].

Native of Auſtria, Sileſia, Italy. Cultivated in 1759 by Mr. Miller [l]. It flowers from June to auguſt.

5. Root perennial, ſpindle-ſhaped. Stem from two to three feet in height, erect, branched, many-flowered, round, ſtriated, roughiſh, purple at the baſe, annual. Root-leaves ſpreading upwards, twice ternate, broader than long: leaflets oppoſite, petioled, variouſly and deeply cut, ribbed, full of net-like veins; their diviſions generally alternate, acute, decurrent, entire, rough at the margin as well as at the ribs on both ſides. Petioles roundiſh, ſtriated, rough, channelled above, dilated and ſomewhat membranous at the baſe. Stem-leaves ſolitary at each diviſion of the ſtem, ſmall, ternate: leaflets ſeſſile, lanceolate, acute, ſcarcely ever lobed: petiole dilated, a little membranous, concave, ſtriated, half embracing. Uppermoſt leaves obſolete, and conſiſting of the membranous petiole only. Umbels erect. General involucre of ſix or eight lanceolate, acute, undivided, ribbed, ſpreading leaves, much ſhorter than the umbel, permanent. Partial like the general, but ſomewhat leſs. Rays ſlender, round, ſtriated, ſmooth. Flowers white, equal, all hermaphrodite. Calyx of five ſmall roundiſh blunt concave leaves. Petals five times as large as the calyx, oblong, acute, turned in, deeply channelled on the back, equal. Stamens the length of the petals, ſpreading. Filaments awl-ſhaped. Anthers roundiſh, twin, yelloviſh. Germ roundiſh, compreſſed, ſmooth, with five ribs on each ſide, and intermediate furrows of nearly the ſame breadth. Styles half as long as the ſtamens, joined together and thick at the baſe, ſpreading in the upper part. Seeds ovate,

[a] Krocker. [b] Gaertner. [c] Hort. kew. [d] Woodville. [e] Woodward. [f] Penn. tour. Lightf. [g] Linn. [h] Gaertner. [i] Hort. kew. [k] Jacquin. [l] Hort. kew.

ſmooth,

smooth, flat on the inside, marked on the outside with five slightly elevated lines [a].

Native only of Cornwall, where it was observed by Ruddle. It grows in thickets, among bushes, and in hedges. This plant eluded the searches of modern botanists till Mr. Pennington found it in 1788 in great plenty near Bodmin. Sir Thomas Gery Cullum, Bart. gathered it there the year following. In 1793 not a single plant was to be found in the field where Mr. Pennington had discovered it, but Dr. Withering found it in another place farther from Bodmin, among furze. Cattle are so fond of it that they eat it down wherever they can get at it [b]. The root contains a yellow resinous juice [c].

6. Root biennial. Stem two feet high, rigid, angular, even. Leaves super-decompound, the upper ones ternate: leaflets three-parted: segments wedge-shaped, gashed, smooth, like those of Parsley, but larger. Petioles with a white membrane at the sides. General involucre one-third of the length of the umbel: rays linear, with a white membrane at the base on both sides, scarcely branched. The first umbel has usually no involucre. Involucels linear, the length of the umbellet. Petals yellowish, inflex-emarginate. Filaments longer than the corolla, with white anthers. Germs even, scarcely striated.

It resembles Parsley, even in smell and taste, but all the parts are thicker and more rigid [d].

Native of Portugal. Introduced in 1766, by Monf. Thouin. It flowers in June and July [e].

7. Root biennial. Stem round, somewhat striated, small in comparison with the umbel, a foot high. Root-leaves a span long: leaflets five or seven, sub-cordate, sessile, serrate, blunt, smooth, more shining underneath; the end one broader, scarcely lobed. Common petiole round, but between the leaflets channelled. Stem-leaves two or three, small, petioled, three-parted, laciniated, linear. Umbel large, stiffish. Umbellets about thirteen. Involucre many-leaved, linear, awl-shaped, reflex, the same number with the umbel. Involucels similar, with seven rays, but one or two interior. Flowers in an umbellet eight or ten, yellow, all fertile. Petals small, turned in. Seeds oblong, subcylindric, striated [f].

The genus is doubtful, the seeds not having been observed in a state of perfection [g].

Native of Majorca and Minorca, and about Rome.

8. The native place of this is not known. It was introduced here about 1780. It flowers in July and August [h].

Several other species of Ligusticum are known, but not sufficiently ascertained. Allione has L. pyrenæum, n. 1320. which Villars calls L. Seguieri, 2. 615.—L. simplex, n. 1322. Villars dauph. 2. 618. Laserpitium simplex of Linnæus—and Daucus aquilegifolia, n. 1392. t. 63. Ligusticum alterum Belgarum. Lob. obf. 447. ic. 736. Lugd. 744.

Villars has ten Ligusticums: having befides fome new species, as L. nobiflorum, which is Smyrnium nobiflorum of Allione, n. 1347. t. 72.—L. Gmelini, which has much affinity to L. austriacum—and L. cuneifolium—referred in this genus Peucedanum Silaus, Athamanta Meum, and Phellandrium Mutellina of Linnæus. In this natural clafs thefe changes may be for ever made without much advantage.]

PROPAGATION AND CULTURE.

Sow the feeds in autumn foon after they are ripe, for when they are kept out of the ground till fpring, they feldom grow the firft year. When the plants are fit to remove, tranfplant them into a moift rich border, at three feet diftance. The roots of Common Lovage will abide many years, and where the feeds are permitted to fcatter, the plants will come up without care. Several of the other forts are only biennial, and die when they have perfected their feeds. They all love a moift foil and fhady fituation.

DESCRIPTION, *&c.*

1. Common Privet is a ſhrub, uſually about ſix feet in height, branched, the bark of a greeniſh aſh colour, irregularly ſprinkled with numerous prominent points: branches oppoſite, the young ones flexible and purpliſh. Leaves oppoſite, on very ſhort petioles, ſmooth on both ſides, perfectly entire, the lower ones at the bottoms of the ſmall branches leaſt. Panicle about two inches in length, cloſe and ſomewhat pyramidal; branches and pedicels appearing villoſe when magnified. Corolla white, but ſoon changing to a reddiſh brown. The flowers are ſweet-ſcented [a].

Berry ſuperior, fleſhy, ſubglobular, ſhining, of ſo dark a purple as to ſeem black. Pulp ſucculent, purpliſh red. Seeds two, rarely one, in each cell, oblong, convex on one ſide, angular on the other, ſmooth, ſhining, dark purple, with a whitiſh umbilicus at top [b].

Privet is found wild in moſt parts of Europe, and in Japan; in woods and hedges: and flouriſhes beſt in a moiſt ſoil. It flowers in July, and the berries ripen in autumn.

Priver, in old Engliſh authors is alſo called Prim, Print, and Primprint. I preſume from its regular appearance, when clipped, as it was formerly. In German it is *Liguſter*. The ſame name obtains in Dutch, Daniſh and Swediſh. In French it is *Troene*. In Ita-

[a] Smith. [b] Wither. arr. [c] Smith. [d] Linn. [e] Hort. kew. [f] Linn. mant. [g] Linn. ſyſt. [h] Hort. kew.

[a] Curtis. [b] Gærtner.

lian, *Ligustro*. In Spaniſh, *Albena*. In Portugueze, *Alfena*. In Ruſſian, *Schoſt*.

In point of utility and ornament few ſhrubs exceed the common Privet. Its chief uſe is to form ſuch hedges as are required in dividing gardens for ſhelter or ornament; and for this the Italian or Evergreen Privet is uſually preferred. It bears clipping well, is not liable to be diſfigured by inſects, and having only fibrous roots, it robs the ground leſs than almoſt any other ſhrub.] It is one of the few plants that will thrive in the ſmoke of London, though it ſeldom produces any flowers in the cloſer parts after the firſt year. It alſo grows well under the drip of trees.

[Privet is not apt to be eaten by cattle: according to Linnæus, kine, ſheep and goats eat it, but horſes refuſe it. Sphinx Liguſtri or Privet Hawk Moth, and Phalæna Syringaria, feed on it in the caterpillar ſtate; and Meloe veſicatorius, Cantharides or Bliſter Beetle is found on it[y]. The leaves are bitter and ſlightly aſtringent. The wood is very hard, and fit for the turner. From the pulp of the berries a roſe-coloured pigment may be prepared. With the addition of alum, they dye wool and ſilk of a good durable green: for this purpoſe they muſt be gathered as ſoon as they are ripe[z]. They continue on the ſhrub till ſpring, and in times of ſcarcity are eaten by different ſorts of birds, particularly the Bullfinch[a].

Privet varies in many reſpects. The leaves ſometimes grow by threes, and ſometimes are enlarged at the baſe;] they are variegated with white and alſo with yellow; they frequently continue green great part of the winter, like the Italian Privet. [The regular number of ſtamens is two, but ſometimes there are three or four in a flower. And it has been found with white berries. Thunberg ſays that in Japan the leaves are ſomewhat broader and more blunt than in the European ſhrub.

β. The Italian or Evergreen variety is made a diſtinct ſpecies by Miller.] It riſes with a ſtronger ſtem; the branches are leſs pliable, and grow more erect; their bark is of a lighter colour; the leaves are much larger, end in acute points, are of a brighter green, and continue till they are thruſt off by the young leaves in the ſpring: the flowers are rather larger, and are not often ſucceeded by berries in England.

[2. Stem arboreous, very much branched, a fathom and half in height. Branches oppoſite, roundiſh, wrinkled, aſh-coloured, from upright ſpreading: twigs rod-like, reſembling the branches. Leaves oppoſite, entire, from ſpreading upright, grooved along the middle above, paler underneath, with a raiſed line, ſmooth, an inch wide, an inch and half long. Petioles round, grooved above. Panicle ſpreading. Under each diviſion, two oppoſite ſmooth bractes, the lower lanceolate, the upper briſtle-ſhaped. Berry the ſize of a pea.

Native of Japan, where it flowers in june and july[b].

3. This is a ſmall tree, about eight feet in height, with diffuſed ſtraight branches. Leaves lanceolate, quite entire, tomentoſe, petioled, oppoſite, dark green. Flowers white, ſmall. Calyx cup-ſhaped, white. Corolla bell-ſhaped, ſpreading; with lanceolate ſegments. Berry very ſmall, brown, containing four ſeeds.

Native of China, about Canton[c].]

PROPAGATION AND CULTURE.

1. This ſhrub is eaſily propagated by laying down the tender ſhoots in autumn. In one year's time they may be removed where they are to remain, or planted in a nurſery for two or three years, where they may be trained for the purpoſes deſigned.

Alſo by ſuckers, which it ſends forth in great plenty. But theſe are not eaſily kept within bounds, nor do they riſe ſo high as thoſe which are increaſed by layers.

Thirdly by cuttings, planted in the autumn on a ſhady border, and in a loamy ſoil.

But the ſtrongeſt and beſt plants are raiſed from ſeeds. Gather the berries when ripe, put them into a pot with ſand, and bury them in the ground, as is practiſed with Holly berries and Haws. After they have laid a year in the ground, take them up and ſow them in the autumn on a border expoſed to the eaſt, where the plants will come up the following ſpring.

The varieties with ſtriped leaves may be increaſed by budding or inarching upon the plain ſort; or by laying down the branches, but they ſeldom ſhoot to faſt as to produce branches proper for this purpoſe. Being more tender, they ſhould have a dry ſoil and a warm ſituation. In a rich ſoil, they ſoon loſe their variegation, and become plain.

The Italian or Evergreen Privet, is now generally found in the nurſeries inſtead of the common one. It is equally hardy, and will thrive in almoſt any ſituation. It is increaſed in the ſame manner; but as it ſeldom produces berries here, they muſt be procured from Italy.

DESCRIPTIONS, *&c.*

Bulb scaly, or as Jussieu describes it, tuberous imbricated with the bases of the leaves. Stem leafy, simple. Leaves simple, entire, alternate or in whorls. Flowers spathaceous, in a spike or a fort of panicle, hanging down in most of the species[a].

1. The common White Lily has a large bulb, from which proceed several fucculent fibres. Stem stout, round, upright, usually about three feet in height. Leaves numerous, long, narrow pointed, smooth, sessile. Flowers large, white, terminating the stem in a cluster on short pedunicles. Petals within of a beautiful shining white; on the outside ridged and less luminous[b].

Native of the Levant. Linnæus assigns it to Syria. Thunberg gives it as a native of Japan, and observes that the corolla is there near a span in length, and

[a] Jussieu. [b] Woodville.

that it varies with a villofe ſtem. Haller inſerts it in the Swiſs Flora: it is not indigenous there, but muſt have eſcaped from a garden. It flowers in June and july, and has been cultivated in England time immemorial. In Gerarde's time (1597) it was in moſt gardens.

The flowers of the Lily were formerly conſidered as antiepileptic and anodyne; a diſtilled water of them was employed as a coſmetic; and oil of Lilies was ſuppoſed to poſſeſs anodyne and nervine powers; but their odorous matter, though very powerful, is totally diſſipated in drying, and entirely carried off in diſtillation either with ſpirit or water, and no eſſential oil can be obtained from them. The roots only are now in uſe: they are extremely mucilaginous, and are chiefly employed in emollient and ſuppurating cataplaſms, boiled with milk or water. Phyſicians however are generally of opinion that bread or meal poultices poſſeſs every advantage of thoſe prepared from the Lily root.]

The principal varieties of the White Lily are,

1. With the flowers ſtriped or blotched with purple.
2. With variegated or ſtriped leaves, or with the leaves edged with yellow.
3. With double flowers.
4. With pendulous flowers, which Miller and others conſider as a diſtinct ſpecies.

The firſt variety has not been in England much longer than the year 1729. It is now become common, but the purple ſtain giving the flower a dull colour, the common white is generally preferred.

The ſecond variety is chiefly valued for its appearance in winter and ſpring: for the leaves coming out early in the autumn, ſpreading themſelves flat on the ground, and being finely edged with a broad yellow band, make a pretty appearance during the winter and ſpring months. It flowers earlier than the plain ſort.

The third variety is of little value, becauſe the flowers never open well, unleſs they are covered with glaſſes; nor have they any of the rich odour of the common ſort.

The fourth variety (β) came originally from Conſtantinople. The ſtalk is much more ſlender; the leaves are narrower and fewer in number; the flowers not quite ſo large, and the petals more contracted at the baſe; they always hang downwards.

The ſtalks are ſometimes very broad and flat (γ), appearing as if two or three were joined together: when this happens, they ſuſtain from ſixty to one hundred flowers, and ſometimes more. This however is merely accidental, for the ſame root ſcarcely ever produces the ſame two years.

[2. Stem round, ſmooth and even, two feet high. Leaves alternate, petioled, acuminate, margined, ſmooth, a hand and half in length, paler underneath, three-nerved or five-nerved. Flower terminating, reflex and hanging down. Corolla white, a hand in diameter. It differs from the preceding, to which it is allied, in having a weaker ſtem, ſuſtaining only one flower; and fewer leaves on the ſtem, remote, very long, petioled and nerved.

Native of Japan[a].

3. Of the Lilies cultivated in this country this is one of the leaſt, the whole plant when in bloom being frequently little more than a foot high. In its native ſoil it is deſcribed as growing to the height of two feet[b]. The ſtalk is terminated by one upright flower. It is purple, ſlender, upright, round, ſmooth with a ſlight glaucous bloom on it, ſolid, ſtiffiſh. Root-leaves few, often only on the barren plant, on long petioles. Stem-leaves numerous, alternately ſcattered, ſeſſile, curved back, narrow-lanceolate, the upper ones gradually more ovate-lanceolate, quite entire, blunt with a purple tip, even on both ſides, ſlenderly nerved, flat, a little fleſhy, ſhrivelling. The flower has no ſcent. Pedunele an inch or an inch and half in length, thicker at top. Claws of the petals pale green, curved in, alternately broader and narrower; borders duſky yellow on the outſide with ſaffron edges, within at the middle of the baſe yellow with dark-ruſt-coloured broad ſpots, the reſt bright ſaffron, thrice the length of the claws, alternately broader and narrower, revolute, ovate-acuminate, quite entire, blunt, even on the outſide with a very fine bloom, within ſmooth. Filaments duſky red, approximating at bottom, recurved a little at top, compreſſed, gradually attenuated, ſmooth. Anthers red, narrow-elliptic, two-celled. Pollen orange-coloured. Germ pale green, narrow, obſcurely three-cornered, even. Style red, about the ſame length with the filaments, three-cornered, ſmooth, a little thickened below the tip. Stigma deep red, club-ſhaped with three obſolete perforations at the corners, very minutely pubeſcent[c].

This Lily was firſt obſerved by Cateſby on open moiſt ſavannas in many parts of Carolina. He ſays that the bulb is about the ſize of a walnut; that the petals turn back in a graceful manner, and are tapering, terminating in points, and edged with ſmall indentures, and that the whole flower is variouſly ſhaded with red, orange, and lemon colours.

Mr. Curtis, to whom roots were ſent from South-Carolina by Mr. Robert Squibb, at the cloſe of the year 1787, informs us, that it varies conſiderably in the breadth of its petals, in their colour and ſpots; and that it flowers uſually in july and auguſt.

4. Bulb ſubovate, conſiſting of thick white looſely imbricate ſcales, putting out a few thick fibres from the bottom. Stem upright, a foot and half high, ſtriated-angular, ſmooth or ſlightly hairy, with numerous ſcattered leaves, the upper ones ſpreading out horizontally, acute, quite entire, obſoletely hirſute, a little rough to the touch, dark green, ſlightly nerved, ſeſſile, lanceolate-linear, three or four inches long: each, excepting the lower, frequently producing a roundiſh ſhining pale-green bulb or two in the axil. Pedunele terminating, round, thick, ſomewhat villoſe; either ſolitary, or two, three or four together, forming a ſort of umbel; ſome naked, others having a bracte or two. Flower without ſcent, red-orange within, pale-orange on the outſide: all the petals from the baſe to beyond the middle are rugged with little ſcales and apophyſes, with a few black dots; the border is ſpreading, but not rolled back; three alternate ones are a little more exterior, lanceolate, narrower, almoſt equally drawn to a point at both ends, the nectareous tubular floccoſe line occupying the whole lower part; the other three, from a channelled claw unfold into a broad-ovate lamina, and have the groove of the nectary continued to the very top. Filaments red. Anthers dark purple. Style red. Capſule ovate, with browniſh ſeeds[d].

Such is the deſcription of the Orange Lily, as it is found wild in Auſtria. It grows in Italy and other ſouthern regions of Europe; in Siberia alſo and Japan. It varies much in ſize, leaves and flowers. Mr. Miller mentions the following varieties.]

1. Orange Lily with double flowers. β.
2. Orange Lily with variegated leaves.
3. Smaller Orange Lily. γ.
4. Bulb-bearing fiery Lily. ε, ζ.

Seldom riſing more than half the height of the others; the leaves narrower; the flowers ſmaller, and of a brighter flame-colour, few in number and more erect. They come out a month before thoſe of the common ſort, and the ſtalks put out bulbs at moſt of the axils, which, if taken off when the ſtalks decay, and planted, will produce plants. There are ſeveral ſubordinate varieties of this: as

1. The great broad-leaved. ι.
2. The many-flowered.
3. The ſmall. κ. *Mill. n. 4.*
4. The hoary bulb-bearing Lily. ο.
5. [This has a pretty large yellow ſcaly root, from which ariſes an upright ſtalk near three feet high, with long narrow leaves, almoſt triangular, having a longitudinal ridge on their under ſide; they are deep green and terminate in acute points. The upper part of the ſtalk divides into four or five pedunels, each ſuſtaining a ſingle flower of a fine carmine colour, with

[a] Woodville. [b] Thunberg. [c] Curtis. [d] Salisbury. [e] Jacquin.

a few dark ſpots ſcattered over it. They appear in July, and when the ſeaſon is not hot, they continue a conſiderable time in beauty [a].

Mr. Miller makes two ſpecies of this. The common Red Martagon juſt deſcribed, and what he calls the Martagon of Pompony [b]: the ſtalks of which riſe higher, the leaves ſhorter, and ſet cloſer upon the ſtalks; each ſtalk ſuſtaining from fifteen to thirty flowers, of a very bright red, approaching to ſcarlet. The peduncles are very long, ſo that the flowers ſpread out very wide. [Parkinſon ſays that he has reckoned ſixty and one hundred flowers on a plant, and that they are of a pale or yelloviſh red. He mentions ſeveral varieties.

Linnæus diſtinguiſhes this ſpecies by its linear, ſharp, three-ſided, channelled leaves, and the chink of the nectary being very much toothed. But Thunberg remarks, that in Japan the leaves are awl-ſhaped, linear and lanceolate on different individuals, and that the corollas in his ſpecimens were ſcarcely revolute.

Native of the Pyrenees, Siberia, Japan and China. It was cultivated in 1629, as appears from Parkinſon [c].]

6. Scarlet Martagon is from three to four feet in height; the leaves are much broader than thoſe of the preceding, and appear as if they were edged with white; they are placed very cloſely upon the ſtalks. The flowers are of a bright ſcarlet, and ſeldom more than five or ſix in number. It flowers late in July, and in cool ſeaſons continues in beauty great part of auguſt.

[Linnæus remarks, that the raceme, before the flowers open, is ſcarcely curved in, as in the preceding and next following ſpecies, and that the ſtem is clothed with cluſtered leaves to the very top.

Mr. Curtis obſerves, that it varies in the number of flowers, from one to ſix, and that the colour in ſome is of a blood red. Jacquin deſcribes the ſmell as diſagreeable; whilſt Scopoli compares it to that of an orange. This ſpecies, not being the Martagon of Linnæus, Mr. Curtis, to avoid confuſion, calls it Chalcedonian Lily.

Native of the Levant, and of the mountains between Carniola and Carinthia; if Jacquin's plant be the ſame with that from the Eaſt.

Cluſius informs us, that it was brought from Conſtantinople to Vienna, before his arrival in that city.—It was cultivated here in 1596, by Gerarde [d].

There are ſome varieties of this in the ſize and colour of the flowers, which are ſometimes of a blood red.

7. Stem round, very ſmooth and even, panicled at top, two feet high and more. Branches alternate, diverticating, upright, like the ſtem, reflex at top, flower-bearing. Stem-leaves alternate, ſubpetioled, folded together at the baſe, ovate-oblong, acute, quite entire, ſmooth, five-nerved beneath, ſpreading. One flower at the end of each branch. Corollas large and handſome. Petals oblong, acute, white with large purple ſpots and ſmaller black ones from the middle to the baſe: nectareous keel bearded [e].

Gouan aſſerts, that the leaves are conſtantly three-nerved.

Cateſby ſays, that the flowers grow alternately on long footſtalks, and that they are of an orange and lemon colour, thick ſpotted with dark brown.]

According to Miller, it riſes with a ſtrong ſtalk from four to five feet high. The flowers are produced in form of a pyramid, and when the roots are ſtrong, there are forty or fifty flowers on a ſtalk; they are large, yellow with dark ſpots, and make a fine appearance, but ſmell ſo diſagreeably, that few perſons can endure to be near them. They appear at the end of june.

[Native of North America. Introduced into England from Penſylvania by Peter Collinſon, Eſq. [a] in 1738 [b].]

8. This riſes with a ſtrong ſtalk from three to four feet high. Leaves broad. Flowers dark purple, with ſome ſpots of black; they are produced in looſe ſpikes, appear in june, and have a diſagreeable odour when near, but not ſo offenſive as the preceding.

[Bulb compoſed of lanceolate, yellow, looſe ſcales, with thick, long, whitiſh fibres at bottom. Stem ſtraight, round, ſhining, from a foot and half to four feet in height, at the top of the bulb furniſhed with rooting fibres in whorls, pale green at bottom, the reſt having black ſpots ſcattered over it; above and below the leaves are ſcattered, but in the middle they are in whorls; lanceolate, acute, ſomewhat nerved, quite entire, ſubpetioled: the ſtem terminates in a looſe raceme, many-flowered, few-flowered, or ſometimes one-flowered only. Peduncles purple, dotted with black, with lanceolate ſharp bractes, two to the lower, and one to the upper flowers. Petals purple or pale, more or leſs ſpotted with black on both ſides, the three outer hirſute with a raiſed line along the middle. Filaments and ſtyle pale. Anthers bay with an orange-coloured pollen. Germ green. Capſule brown [c].

Native of the South of Europe, and Siberia.—Cultivated in 1596, by Gerarde [d].]

8. The leaves of this are narrower; the whorls ſtand farther aſunder; the leaves and ſtalks are ſomewhat hairy, and the buds of the flowers are covered with a ſoft down; the flowers are of a brighter colour, with few ſpots, and come out earlier, though the ſtalks appear much later above ground. It flowers early in june. Mr. Miller makes a diſtinct ſpecies of it under the name of L. hirſutum or Red Martagon. Theſe flowers in old gardens are known by the name of Turk's Caps.

9. Bulbs oblong and large. Stems from four to five feet high. Leaves oblong, pointed. Flowers large, yellow ſpotted with black, ſhaped like thoſe of the Orange Lily, and the petals not turned back ſo much as in the other Martagons. They come out in the beginning of auguſt, and when the roots are large, in great numbers, making a fine appearance. There is a variety of this with larger deeper-coloured flowers.

[Linnæus obſerves that the leaves are marked with three lines, and that the corollas are rolled back, yellow at the baſe with black dots.

On the ſummit of the ſtem, according to Cateſby, are about twelve pendulous flowers on long arched peduncles; the petals are reflected very little, not more than thoſe of the common White Lily.

Thunberg ſays that the leaves are lanceolate, nerved beneath, upright, an inch in length; corolla bell-ſhaped, bent back at the tips only, purple ſpotted.

This, ſays Parkinſon, was brought into France from Canada by the French colony, and thence into us, in 1629. It flowers in july and auguſt [a]. It is found in other parts of North America; for Cateſby ſays it was ſent to Mr. Collinſon from Penſylvania, and flowered ſeveral years in his garden. Thunberg alſo obſerved it in Japan.

10. Bulb roundiſh, ſmall. Stem quite ſimple round, even, a foot high. Leaves lanceolate or lanceolate-linear, ſeſſile, four or ſix, ſtriated, rather blunt, even, upright; two or three of the upper ones uſually alternate, narrower. Flowers terminating, few, an inch and half in diameter, on very ſhort, naked, almoſt upright peduncles. Petals ovate, blunt, even, ſtriated, purple, not rolled back, attenuated at the baſe. Filaments ſhorter by half than the corolla. Anthers upright. Germ triangular, oblong. Style none. Stigmas three, oblong, curved back, almoſt the length of the germ. Leaves as in the Martagons: but the flowers ſmall, the ſize and form of Lilium perfcum, or Fritillaria perſica. The oblong ſtigmas without a ſtyle are ſingular in this genus [c].

Native of Kamtſchatka, and alſo of China and Cochinchina, if Loureiro's plant be the ſame.]

11. Root ſmaller than in the other ſorts, ſcaly and white. Stem ſingle, upright, near a foot and half high. Leaves in four or five whorls, ſhort, pretty broad, obtuſe. Stem terminated by two flowers which ſtand

[a] Mill. fig. [b] Hort. kew. [c] Ibid. [d] Thunberg. [e] Cateſby. [a] Hort. kew.

[a] Jacquin. [b] Hort. kew. [c] Ibid. [d] Linn. amoen. and Loureiro.

erect,

erect, upon short separate peduncles; they are shaped like those of the bulb-bearing fiery Lily, but the petals are narrower at their base, so that there is a considerable space between them, but upwards they enlarge and approximate, forming a sort of open bell-shaped corolla, but they terminate in acute points: they are of a bright purple colour, marked with several dark purple spots towards the base. It flowers in July, and the seeds ripen at the end of September.

[Linneus observes that it resembles the preceding very much, but the petals of that are ovate and sessile, whereas in this they are on oblong distinct claws.

Thunberg says, that the lower leaves are alternate, the upper ones three or four together, oblong, nerved underneath, an inch and half long.

Native of North America, and also, according to Thunberg of Japan. Linneus marks it as growing in Canada. Mr. Miller says, that it was sent to him from Pensylvania, by Mr. John Bartram. [Mr. Miller cultivated it in 1757, as appears from his figures'.

The species may be distinguished by the following table.

- Leaves scattered, alternate.
  - 1 to 7. Flowers upright.
    - 1, 3, 4.
      - 1. Flowers several. White.
      - 3. Flower one. Orange-yellow spotted.
      - 4. Flowers commonly several. Orange-coloured, rugged within.
    - Flowers reflex.
      - 2, 5, 6, 7.
        - Solitary, White. 2.
        - Several.
          - Red. 5.
          - Scarlet. 6.
          - Yellow. 7.
  - Leaves in whorls.
    - 8 to 11. Flowers reflex. 8, 9.
      - Petals revolute. Purple. 8.
      - Petals reflex at the top only. Yellow-spotted. 9.
    - Flowers upright. 10, 11.
      - Few. Stigmas oblong without a style. 10.
      - Two. Petals with distinct claws. 11.]

PROPAGATION AND CULTURE.

1. The common White Lily, with all its varieties, (and indeed all the sorts) may eafily be increafed from offsets, which the bulbs of this fend out in fo great plenty, as to make it neceffary to take them off every other, or at moft every third year, to prevent their weakening the principal bulb. The time for removing them is the end of auguft, ſoon after the ſtalks decay. They will thrive in almoft any ſoil and ſituation, and as they grow tall and ſpread, they muſt be allowed room, and in large borders they are very ornamental. They are ſo hardy that no froſt injures them; and increaſing very faſt by offsets, are become ſo common as to be little regarded, notwithſtanding the great beauty of the flowers, and their rich odour, which indeed is too powerful for many perſons.

2. The common Orange Lily is ſo common, and increaſes ſo readily by offsets, that it is almoſt rejected, however in large gardens it ſhould not be wanting, ſince it makes a handſome appearance when in flower, if properly diſpoſed.

The ſtalks decaying in ſeptember, the roots may be then tranſplanted, and the offsets taken off; but as it does not put out new leaves till towards ſpring, this may be done till near Chriſtmas. It ſhould be repeated once in three years. This ſort will thrive in any ſoil or ſituation, but will be ſtrongeſt in a ſoft gentle loam, not too moiſt.

The bulb-bearing varieties may alſo be increaſed without taking up the roots, by means of the little bulbs that are put forth in plenty from the axils of the leaves.

Both theſe ſorts, with their varieties, will thrive under the ſhade of trees, and are therefore proper to be introduced in plantations, and on the borders of woods.

5, 6, 7, 8, 9. All theſe may be propagated by offsets, which ſome produce in great plenty, but others ſend out very few, and are therefore more ſcarce. The roots may be taken up when the ſtalks decay; and if there be a neceſſity for keeping them out of the ground, to tranſport them to a diſtant place, they ſhould be wrapped in dry moſs, and they will keep thus for two months. The beſt time to replant them is the beginning of october, but if the ground be not ready to receive them, they ſhould be covered with dry ſand or wrapped in moſs, to prevent the ſcales from ſhrinking, which weakens the bulbs, and often occaſions them to be mouldy and to rot.

The roots ſhould be planted five or ſix inches deep in the ground, eſpecially if the ſoil be light and dry; but where it is moiſt, raiſe the borders five or ſix inches; for if the water come near the roots in winter, it will rot them; and where the ſoil is ſtiff and binding, mix a good quantity of ſea-coal aſhes or rough ſand with it.

As the Canada, Pomponian and Philadelphian Martagons, (9, 5, 11) are ſomewhat more tender, in very ſevere winters, the ſurface ſhould be covered with old tanner's bark or ſea-coal aſhes, to ſecure them from froſt, and in the ſpring the covering may be removed, before the ſtalks ſhoot up.

The tall-growing ſorts are only proper for large gardens, and may be intermixed with white and orange Lilies, tall-growing Irides, and other flowers of the ſame growth; where, if they be not too much crouded, and are properly diſpoſed, they will make a good appearance. Some of the common Martagons thrive under the ſhade of trees, and may therefore be diſpoſed to advantage in plantations.

None of the bulbs ſhould ever be tranſplanted after they have made ſhoots, for it weakens them ſo as not to recover in leſs than two or three years.

In Holland they raiſe a great variety of Martagons. Thoſe which are moſt generally found in the Engliſh gardens are,

The common Martagon with double flowers.
The White.
The Double White.
The White Spotted.
The Imperial.
The Early Scarlet.
The Conſtantinople Vermillion Martagon.

The way of obtaining theſe and other varieties, is by ſowing the ſeeds of the beſt flowers, in ſquare boxes, ſix inches deep, with holes bored in their bottoms, and filled with freſh light ſandy earth. The beginning of october, ſoon after the ſeeds are ripe, is the proper ſeaſon. Sow them pretty thick, covering them about half an inch with light ſifted earth. Place the boxes where they may have the morning ſun only, and refreſh them often with water, if the ſeaſon prove dry. In november remove them where they may have as much ſun as poſſible, and be ſcreened from wind. About the beginning of april remove them into their former poſition, for now the young plants, which are impatient of heat, will appear; and the earth will dry too faſt, if expoſed to the full ſun at noon. Keep them entirely clear from weeds, and refreſh them gently and cautiouſly with water, when the ſeaſon is dry. Let the boxes remain till the beginning of auguſt. Then prepare ſome beds of freſh light earth, and theſe being levelled, take the earth out of the boxes, with the ſmall bulbs, and ſtrew it equally over the beds, covering it half an inch thick with fine ſifted earth. If the ſeaſon prove hot and dry, ſhade the beds in the middle of the day, and refreſh them with water.

If the following winter ſhould prove ſevere, cover the beds with peaſ-haulm or other light covering, to keep out the froſt; but this will be injurious to the bulbs in mild weather.

At the end of february, or the beginning of march, when hard froſts are over, gently clear off the earth upon

upon the ſurface of the beds, and ſift a little freſh earth over them; but in doing this do not diſturb or injure the bulbs. Keep them clear from weeds; water them gently in dry weather; and in very hot days ſhade them from the ſun. When their leaves are quite decayed, ſtir the ſurface of the beds again; and in ſeptember ſift more freſh earth over the beds. During winter and ſpring manage them as before directed.

In ſeptember following tranſplant the bulbs to a greater diſtance, on beds prepared as above. Place them about eight inches aſunder, with the buds uppermoſt, and four inches deep. This ſhould be done in moiſt weather.

In ſevere froſt cover the beds with peas-haulm or decayed tan, taking it off in ſpring, and refreſhing the beds as before with new light earth.

The ſecond year after being planted in theſe beds, the ſtrongeſt bulbs will begin to flower. Then place a ſtick wherever you obſerve any peculiar varieties, and when the leaves are decayed, remove theſe bulbs into other beds at a greater diſtance, or into the borders of the flower-garden. But never reject any till they have flowered two years; for frequently ſome will make a mean appearance the firſt year, and afterwards become fair handſome flowers when they have obtained ſtrength. When ſuch have been ſelected as are worth preſerving, the reſt may be planted in ſhady outer walks, or in the borders of plantations.

[3. Cateſby's Lily may be raiſed from ſeeds, or offſets, which however are not very plentifully produced; nor will it grow in perfection without great care: the roots in particular are to be guarded againſt froſt. The ſoil and ſituation may be the ſame as recommended for Cyclamen coum [1].]

11. This ſort growing in a ſmall compaſs, and the flowers having no ill ſmell, is proper for the borders of ſmall gardens. The ſtalks decay ſoon after the ſeeds are ripe. This is the proper time to remove the roots, which do not put out new fibres till after Chriſtmas. The bulbs do not put out many offſets.

L. capenſe. *Thunb. prodr. cap.* 68.

Leaves ovate with a ſtrong midrib underneath tomentoſe.

3. Limeum æthiopicum.

Thunb. prodr. cap. 68.

Leaves linear-lanceolate.

DESCRIPTIONS, *&c.*

1. Stature of Corrigiola or Telephium. Stems proſtrate, weak, a ſpan long, angular, naked, perennial at the baſe. Leaves alternate, remote, linear-lanceolate, ſmall. Corymbs terminating, ſolitary, compound, naked, on long peduncles [2].

The leaves, ſo differently deſcribed above, ſeem to vary much. In the ſpecimens of the Bankſian herbarium, we have linear, oblong, ovate, roundiſh, and ſpatulate leaves, if the ſpecimens be all of one ſpecies.

According to Gærtner, pericarp none. Seeds naked, united into a ſpherical fruit, ſpontaneouſly ſplitting when ripe. Seeds erect, dirty ſtraw-coloured, on one ſide convex, excavated and rugged, and having a wide cavity on the other: outer coat coriaceous, of a middling thickneſs: inner very thin, pale: embryo of the ſame ſhape with the ſeed, or meniſcus-form, farinaceous, very white: embryo roundiſh, ſemicircular, milky: cotyledons ſemicylindric; radicle long, bowed, inferior.

Introduced in 1774, by Mr. Francis Maſſon [3].

2. This ſeems to be a ſmall plant, as far as we can judge from Maſſon's ſpecimen in the Bankſian herbarium. It is extremely woody at bottom. The leaves are all ovate, ſubpetioled, and as lanuginoſe as thoſe of Mullein. I am at a loſs to account for the younger Linnæus giving it the name of *aphyllum*, and ſaying that it ſeems to be leafleſs, when he has deſcribed them as ovate and ſeſſile, and there are abundance of root-leaves, and no want of ſtem-leaves.

3. Of this we have no deſcription; but it is only mentioned by Thunberg in his prodromus. We have here a deplorable inſtance of the inſufficiency of trivial names, in *africanum, capenſe, æthiopicum*, which diſtinguiſh nothing; all theſe plants being natives of the Cape of Good Hope.

There is a fourth ſpecies in the Bankſian herbarium, ſent from the ſame country by Maſſon, which is truly a ſhrub, and may be called *Limeum fruticans.*

Scape round ſtriated jointed like a necklace ſimple, leaves linear acute.

10. Limodorum virens.
Roxb. corom. 2. 32. *t.* 38.
Root ſcaly, ſcape branched ſpotted, bractes acute, flowers remote greeniſh yellow.

11. Limodorum recurvum.
Roxb. corom. 2. 33. *t.* 39.
Root tuberous, ſcape bending nodding, ſhorter than the leaves, leaves broad-lanceolate five-nerved, ſpike globular nodding.

12. Limodorum mutas.
Roxb. corom. 2. 33. *t.* 40.
Root tuberous, ſcape arched longer than the leaves ovate five-nerved, ſpike oblong pendulous.

13. Limodorum aphyllum.
Roxb. corom. 2. 34. *t.* 41.
Root fibrous: leafleſs, flowers ſolitary naked, ſeſſile.

DESCRIPTIONS, *&c.*

1. Root tuberous. Stem a foot and half high. The number of flowers not exceeding five, dark purple. In a more luxuriant ſtate, it is probably a larger plant, and produces more flowers [a].

Native of North America; as Virginia and South Carolina.—Introduced in 1788 by Mr. Curtis, from bog earth brought over with plants of Dionæa Muſcipula [b].

This ſpecies was long confounded with the next.]

2. Root ſhaped like that of the true Saffron, but the outer cover of a darker brown colour; from this come out two or three leaves, nine or ten inches long, and near three quarters of an inch broad in the middle, being contracted towards both ends, terminating with long acute points, folding over each other at their baſe; they have five longitudinal furrows, like the firſt leaves of young Palms. The flower ſtalk ariſes immediately from the root, on one ſide of the leaves, it is naked, ſmooth, and of a purpliſh colour towards the top. It is near a foot and half high, and terminated by a looſe ſpike of purpliſh red flowers on ſhort peduncles.

[Bulb tubercled, roundiſh, of a fleſhy and fibroſe ſubſtance, covered with a coriaceous ſhining ſkin, and having ſome tomentoſe white fibres underneath. Leaves from the bulb, vernal, two feet long, broad-lanceolate, longitudinally folded at the nerves, even, very like thoſe of a young plant of the Coco Palm. Scape ſimple, upright, ſometimes ſubdivided at top, two feet high, even, round. It has little ſheaths on it, which are remote, præmorſe, embracing, netted, pale. Flowers terminating, ſcattered, alternate, large, purple, ſometimes varying to white. The three outer petals are upright, ſpreading; the two inner bent in, forming a helmet with the middle upper one; all equal, converging a little, the inner ones paler. Nectary ventricole, cordate, embracing the column with its baſe; lip recurved two-lobed whitiſh, with longitudinal blood-red grooves, and others ſulphur-coloured; the middle appendiched with an ovate emarginate blood-red little jag. Column elongated, gibbous, boat-ſhaped, dilated at top, cordate, having the two anthers on very ſhort pedicels in a caſe, ſtigma tubular in front. Germ oblong, attenuated. Capſule large, oblong, pedicelled, attenuated at the baſe [c].

According to Swartz, this is the tenth Satyrium of Browne, who calls it *Jamaica Salep*, and recommends the root, properly cured, as a ſtomachic.

Native of the Weſt Indies, particularly Jamaica, in the cooler parts of the mountains. It was ſent to Mr. Miller by Dr. Houſtoun, and therefore was cultivated by him at Cheſſea before 1733, in which year Dr. Houſtoun died.] Mr. Miller ſays he alſo received the roots from the Bahama iſlands, and from Penſylvania. Probably this might be the firſt ſpecies. He alſo mentions that he received a ſpecies from Maryland with oval obtuſe leaves, of a thicker conſiſtence.

L. altum ſometimes flowers here in april and may, ſometimes not till ſeptember or october, but the moſt uſual time of flowering is june and july. [In Jamaica it flowers in ſummer.

3. Monſ. L'Heritier obſerves, that although the lip of the nectary in this ſplendid plant ends behind in a very ſhort ſpur, it ought not however to be ſeparated from this genus.

Native of China. Introduced about 1778 by John Fothergill, M. D. It flowers in march and april [d].

4. Native of Jamaica and St. Domingo.

5. Native of Jamaica [e].

6. See the deſcription under Epidendrum ſtriatum.

7. See the deſcription under E. enſifolium. It is a native of China and Japan, and was cultivated here in 1780, by John Fothergill, M. D.

The ſcape is not anciptal or two-edged, but round, and it has no horn to the nectary.

8. This is *Orchis falcata* of Thunberg's flora japonica. Leaves radical, ſeveral, equitant, convoluted, revolute-ſickled, ſmooth, a finger's length, the lower ones ſhorter. Scape upright, ſmooth, ſhorter than the leaves. Flowers in ſpikes, terminating.

Native of Japan [f].

9. See the deſcription under Epidendrum moniliforme. It is not paraſitical, but grows on walls and in hedges. The ſheaths of the leaves have ſeveral ribs [g].

10. Bulbs many, connected near the baſe, conical, pointed, ſurrounded with the circular marks of the inſertions of the leaves, greeniſh, many fleſhy fibres iſſuing from the baſe. Leaves all radical, ſeveral, linear, ſlightly nerved, nearly the length of the ſcape, about an inch broad, ſmooth. Scape axillary, erect, often branched, from one to two feet high, round,

[a] Curtis [b] Ibid. [c] Swartz. [d] Hort. kew. [e] Thunb. jap. [f] Ibid. and Linn. tranſ.

ſmooth,

ſmooth, coloured with purple ſpots; here and there a ſheathed acute bracte. Flowers ſtriated: petals nearly equal, erect or aſcending. Under lip of the nectary projecting, broader but ſhorter than the petals, laterally lobed: lobes involute: middle diviſion large, heart-ſhaped, fringed.

Native of Coromandel, on dry uncultivated ground, flowering during the cold ſeaſon.

11. Bulbs ſtriated, nearly round, ſurrounded with one or two rings, and having many thick fleſhy fibres from their lower parts. Stem from the ſide or baſe of the bulb: it is no other than the ſheathed petioles of the three or four leaves united, ſcarcely appearing above ground. Leaves ſlender in ſubſtance, a little waved round the margins, ſmooth, from ſix to twelve inches long, and three or four broad. Scape from the ſame part of the bulb with the ſtem, and even ſometimes involved in the lowermoſt ſheath or two of the ſcape, about ſix inches long, or rather leſs than half the length of the leaves; a few ſheaths ſurrounding it here and there. Spike many-flowered, with the apex directed to the ground. Bractes ſeſſile, ſtraight, lanceolate, one to each flower. Flowers numerous crowded, white with a ſmall tinge of yellow. Petals nearly equal. Under lip of the nectary broad; apex rounded, undivided, ſhovel-form, crenulated: horn ſcarcely any.

Native of Coromandel, in moiſt valleys among the hills, flowering at the beginning of the rainy ſeaſon.

12. This differs from the preceding in having the bulbs ſmooth, the leaves oval, the ſcape longer than the leaves, the ſpike oblong and pendulous, with the flowers at ſome diſtance from one another, of a beautiful roſe-colour, and the under lip of the nectary ſharp-pointed.

Native of the ſame places, and flowering at the ſame time.

13. Stems perennial, ſeveral, moſt ſimple, ſpreading or pendulous as the ſituation admits, naked, round, jointed at every inch, and at each joint ſmall membranaceous annular ſcales, without the leaſt veſtige of a leaf. Flowers generally iſſuing ſingle from the joints of the ſtems. Nectary large, near the baſe, the ſides incurved, ſo as to form as it were a tube, the exterior part expanded, margins curled, waved and ciliated: it is of a pale purple colour.

Native of Coromandel but very rare there, on dry rocky hills, flowering in the beginning of the hot ſeaſon [1].

PROPAGATION AND CULTURE.

1. From the little experience we have had of the management of this ſpecies, it appears to be ſcarcely hardy enough for the open border, yet not tender enough to require a ſtove. The firſt plants were produced here by planting the roots in pots filled with hog earth, and plunging them into a tan-pit which had a gentle heat, for the purpoſe of raiſing plants or ſeeds, and for ſtriking cuttings.]

2, &c. The other ſorts are much too tender to thrive in the open air in England, and ſeldom flower in a greenhouſe. They are kept therefore in the tan-bed in winter, and if in ſummer the pots be plunged in a tan-bed under a deep frame, the plants will thrive, and flower ſtrongly.

They are propagated by offsets from the roots, which are ſent out pretty freely (from the ſecond ſort) when the plants are in vigour. Theſe ſhould be taken off and tranſplanted, when the plants are moſt deſtitute of leaves. They ſhould have a ſoft loamy ſoil, and little water, eſpecially in winter.

Tjeru-Catu-Naregam. *Rheed. mal.* 4. 31. *t.* 14.
Leaves alternate or faſcicled: leaflets two or three pairs with broad-winged petioles, ſpines ſolitary.

DESCRIPTIONS, &c.

1. Leaves oblong-ovate. Spines axillary, ſolitary. Peduncles axillary, cluſtered, one-flowered [a]. Petals four. Stamens eight, monadelphous [1].

Trunk irregular, with a ſmooth greeniſh-aſh-coloured bark. Branches numerous very irregular. Spines very ſtrong and ſharp, but in many plants entirely wanting. Leaves alternate on ſhort petioles, emarginate, ſmooth, firm, from two to three inches long, an inch or an inch and half broad. Stipules awl-ſhaped. Racemes ſhort. Bractes awl-ſhaped, ſmall. Calyx four or five-parted. Corolla four or five-petalled: petals oval, equal, ſpreading. Nectary cylindric, with a ten-toothed mouth; teeth alternately longer; the anthers reſt on theſe teeth, without any filaments. Germ globular: ſtyle the length of the nectary: ſtigma four or five-lobed. Berry ſize of a nutmeg, very like a Lime, whence comes the Hindoo name Adavie-nima, or wild Lime. It is commonly four-celled, and the ſeeds are generally ſolitary.

Native of Coromandel, in the large foreſts on the coaſt, where it grows to a ſmall tree, though oftener found in the ſtate of a large ſhrub [a]. —Introduced in 1777, by Dan. Charles Solander, L.L.D. [2]

2. Native of the iſland of Mallicollo in the South Seas [3].

3. This tree has the appearance of an Orange, with flexuoſe branches. Leaves alternate, petioled, quite entire, have pores ſcattered over them, the ſame ſize with thoſe in Jaſminum fruticoſum: lateral leaflets ſeſſile, the middle one larger, emarginate. Spines ſtipular, longer than the petiole. Berry pedunculed, globular, ſmooth, red, the ſize of thoſe of Vaccinium [4].

[a] Linn. mant. [1] Juſſieu. [2] Roxburgh. [3] Hort. kew. [4] Forſter. [5] Linn. mant.

[1] Roxburgh.

Juſſieu informs us that he has ſeen this ſpecies with three petals and five ſtamens. Jacquin deſcribes it with three petals and ſix ſtamens, and remarks that in a few flowers he obſerved four petals and eight ſtamens.

According to him, the whole tree is ſmooth, the height of a man (in the ſtove), with a trunk the thickneſs of the human arm, covered with a browniſh aſh-coloured bark, very much branched, the branchlets alternate, ſpreading. Spines awl-ſhaped, ſtraight, ſpreading, on each ſide at the leaves and branchlets, the older ones near half an inch long. Leaves ſubbifarious, on very ſhort petioles, ſhining: leaflets blunt, retuſe, very obſcurely crenate, with pellucid dots on both ſides; the lateral ones ovate, half an inch long; the middle one lanceolate, an inch and more in length. Flowers ſweet-ſmelling, on very ſhort peduncles, axillary, in pairs or three together, ſucceeding each other ſlowly. Calyx ſomewhat villoſe, green. Corolla and filaments white. Anthers pale yellow. Stigma yellow. Fruit red-bay, ſoft, the ſize of a hazel nut. Pulp colourleſs, very ſweet, with a ſlight taſte of turpentine; before it is ripe glutinous and taſting ſtrong of turpentine. Seeds pale coloured with green and purple, large, ſmooth, containing a green, two-lobed kernel, of an unpleaſant acrid taſte. One or two ſeeds only uſually ripen; and then the partitions are ſo preſſed together, that the number of cells cannot eaſily be diſcerned.

The calyx is bell-ſhaped, blunt, with a trifid mouth. The anthers are oblong and incumbent. Germ oval, obſcurely three-cornered. Style filiform, upright, longer than the ſtamens. Stigma three-lobed-headed. Berry roundiſh, five-celled. Seeds ſolitary, oval, compreſſed a little.

Loureiro deſcribes his Triphaſia, which, ſuppoſing it to be of a new genus, he named from the prevalence of the number three in the leaves, corolla and calyx, as a tree of five feet in height, with abundance of ſpreading, twiſted, ſubdivided branches; the leaflets ovate, emarginate, flat, ſmooth, ſmall, odoriferous, of a browniſh green colour. Prickles axillary, ſtraight, very ſharp, ſhorter than the leaves. Flowers white, axillary, ſolitary, with thickiſh petals. Berries red, ovate, like thoſe of Coffee, but only half the ſize, covered with a thin pellicle, and containing a clammy, ſweet, inodorous, eatable pulp, and a ſingle ovate ſeed.

It is a native both of China, and Cochinchina, where it is much cultivated both for the beauty and ſmell, and the pliancy of its branches. Jacquin's plant alſo came originally from China, though immediately from the iſland of Mauritius. He ſays that it flowers very well in the open air from may to july, and bears abundance of fruit in ſeptember[a]. According to Burman it is a native of Java.

4. Leaves alternate, ovate, acute, entire, the ſize of Citron leaves. Partial petioles ſhort, winged, but the wings bent in. Racemes ſhort, compound. Flowers minute. Calyx five-toothed[b].

Trunk ſcarcely any, with an aſh-coloured bark. Branches numerous, nearly erect. Leaves in threes, four or fives, but generally in fives, feather-form: leaflets alternate, oblong, ſmooth, ſhining, from two to three inches long, and about an inch and half broad. Petiole round, ſmooth. Racemes terminating and axillary, often compound, covered with a ruſt-coloured down. Bractes ſmall concave, one under each ſubdiviſion of the raceme. Flowers white, very fragrant. Nectary a notched ring ſurrounding the baſe of the germ. Filaments ſwelled at the middle, alternately ſhorter. Berry round, red, ſmooth, ſize of a ſmall cherry, pulpy. One or two ſeeds only come to maturity, though the germ has always the rudiments of five.

It is an elegant fragrant ſhrub, very common in moſt uncultivated lands in Coromandel, but chiefly under large trees, where birds have dropped the ſeeds. It flowers all the year there. The whole plant, when drying in the ſhade, diffuſes a pleaſant permanent ſcent; the flowers are exquiſitely fragrant; birds eat the berries greedily.

5. This tree is ſaid to attain the height of thirty feet, with a trunk ten inches in diameter. The leaves have the ſmell of Aniſe, and ſo has the fruit, whence Rumphius calls it *Aniſum moluccanum*. Spines ſtraight, acute, in the axils between the branch and the petiole. Common petiole or rachis membranaceous, jointed. Leaflets obovate, oppoſite with an odd one, ſmooth, emarginate. There are no ſpines on the petioles. Perianth very ſmall, five-cleft. Petals five, ſpreading. Filaments eight or ten, with thick anthers. Germ roundiſh. Style thick, ſhort.

Native of the Eaſt Indies[c].

6. Leaves alternate, in fives: leaflets alternate ſmooth, five inches long, and about two broad. Panicles terminating, and from the exterior axils. The reſt as in L. pentaphylla.

The berries are alſo eaten by birds, and the flowers are equally fragrant with thoſe of the fourth ſort. In their habit theſe two agree, and the ſerrate leaves are the chief diſtinction.

Native of the mountainous parts of the Circars, where it grows to a middle-ſized tree, with a large branching head.

7. Leaves on the young ſhoots alternate, on the woody branchlets faſcicled, feathered with an odd one, three to four inches long. Leaflets two or three pairs, oppoſite, ſeſſile, oblong, nearly equal, ſlightly notched, obtuſe, ſmooth, of a ſlight texture, covered with numberleſs ſmall diaphanous points; one inch long and half an inch broad. Petiole broad-winged, leaf-like, jointed. Flowers white, ſmall, fragrant, collected in ſmall umbels or racemes over various parts of the branchlets. Calyx four-toothed. Petals four, lanceolate, ſpreading. Nectary a ring ſurrounding the baſe of the germ. Filaments eight, rather ſhorter than the petals, broad towards the baſe, ſpreading. Anthers incumbent, oval. Germ ſeſſile. Style thick, ſhorter than the ſtamens. Stigma oblong. Berry the ſize of a large pea, ſmooth, juicy, when ripe black, four-celled. Seeds four, but it ſeldom happens that all come to maturity.

Native of Coromandel, on the low lands near the coaſt. It is there a ſhrub, but in the mountains it grows to a middle-ſized tree. It flowers in the hot ſeaſon[d].

2. Limoſella diandra.

Lin. ſyſt. 572. *Reich.* 3. 181. *mant.* 252. *Krock. ſilef. n.* 1006.

Leaves ſubulate.

DESCRIPTION, *&c.*

1. Root annual, throwing out naked cylindrical proſtrate runners, which take root at their extremities, and form new plants. Leaves radical, on long foot-ſtalks, ſpatulate, ſmooth, entire. Flowers ſmall, radical, on ſimple flower-ſtalks, which become inflexed as the fruit ripens. Segments of the the calyx ſharp, the two uppermoſt leaſt deeply divided. Corolla with a ſwelling tube; the limb in five equal ſegments, whitiſh without, red on the inſide, the two uppermoſt of which are a little inflexed. Stamens aſcending, divaricated in pairs towards each ſide of the flower. Style declining, with a blunt rough ſtigma. Capſule globular, with a groove along its upper ſide. Seeds very numerous [a].

Linneus remarks, that the leaves are involute. Dr. Smith ſays he has not found them ſo.

Native of many parts of Europe, in muddy and gravelly places liable to be flooded, and where water has ſtood during the winter. Flowering from july to ſeptember.

2. This has entirely the habit of the preceding, but it is only one-fourth of the ſize, ſo that it is one of the leaſt plants we are acquainted with. It increaſes like the laſt by runners, and theſe are very ſhort. Leaves radical, linear, ſcarcely widening in the middle, blunt at the end. Scapes capillary, one-flowered, the length of the leaves. Stamens no more than two.

Found by Koenig at the Cape of Good Hope, on the coaſt [b].

LINCONIA.

Lin. gen. Reich. n. 335. *Schreb. n.* 433. *Mant.* 147. *Juſſ.* 442.

Claſſ. 5. 2. Pentandria Digynia.

GENERIC CHARACTER.

CAL. *Perianth* inferior, four-leaved: *leaflets* ovate, permanent: the inferior oppoſite pair ſhorter.

COR. *Petals* five, lanceolate, ſeſſile, upright.

Nectary, a dell impreſſed on the bottom of the petal, girt beneath by the margin.

STAM. *Filaments* five, awl-ſhaped, margined, upright, middling. *Anthers* obtuſe, ſagittated with nutant, gaping auricles.

PIST. *Germ* half-inferior with reſpect to the corolla; with reſpect to the calyx, ſuperior. *Styles* two, filiform, ſtriated. *Stigmas* ſimple.

PER. *Capſule* two-celled.

SEEDS two?

OBS. *The Perianth perhaps might be taken for Bractlets; and then the flower would be entirely ſuperior.*

ESSENTIAL CHARACTER.

Petals five, with a nectareous excavation at the baſe. *Capſ.* two-celled.

SPECIES.

1. Linconia alopecuroidea.

Lin. ſyſt. 261. *Reich.* 1. 615.

Coridis folio & ſpica africana ſtrutex alopecuroides, flore albo. *Herm. afric.* 7.

DESCRIPTION, *&c.*

This is a ſhrub with wandlike branches, irregular from the baſe of the falling leaves, as in the Fir-tree. Branches few, determinate. Leaves ſcattered, in a ſort of whorl, five or ſix together, ſubpetioled, linear, three-ſided, ſtiffiſh, ſhining, an inch long, rugged at the angles; the uppermoſt ciliate. Flowers at the ends of the branches, not however in bundles but ſeparate, lateral, ſeſſile, the length of the leaves. Leaflets of the calyx not diſpoſed in a ring, but by pairs alternately oppoſite, villoſe at the edge. Corollas tenacious, fleſh-coloured or white.

Native of the Cape of Good Hope, in watery places among the mountains.

There is another ſpecies from the ſame country in the Bankſian herbarium, with the flowers in bundles and heads.

LINDERA. (*So named by Thunberg, from J. Linder, a Swede, who publiſhed* De Heſperidum pomis, Aboæ 1702. Liber de Venenis, Leid. 1708. 12°. Lipſ. 1739. 8°. Swenſka fargakonſt, &c. Stockh. 1720. 8°. Flora Wikſbergenſis, Stockh. 1728. 8°.

SPECIES.

1. Lindera umbellata.

Lin. ſyſt. 339. *Thunb. jap.* 145. *t.* 21.

Kuro Nosji. *Kæmpf. amoen.* 5. 908.

DESCRIPTION, *&c.*

Stem ſhrubby, looſe. Branches and branchlets alternate, flexuoſe, ſmooth, ſpreading very much. Leaves aggregate at the ends of the branchlets, petioled, oblong, acute, entire, above green and ſmooth, underneath pale and villoſe, an inch long. Petioles ſcarcely a line in length, villoſe above. Flowers terminating, in a ſimple many-flowered umbel. Peduncles a little hairy, unguicular. Pedicels tomentoſe, about half the length.

The Japoneſe uſe the wood for making ſoft bruſhes to clean their teeth with [c].

LINDERNIA. (*So named by Alliani, from Franc. Balthaſ. à Lindern, phyſician at Straſburgh, author of Hortus Aſiaticus* 1747.)

Lin. gen. Reich. n. 828. *Schreb. n.* 1031. *Mant.* 154. *Juſſ.* 122, 450.

Claſſ. 14. 2. Diclynamia Angioſpermia.

Nat. order of *Perſonatæ. Scrophulariæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* five parted: *diviſions* linear, ſharp, permanent.

COR. one-petalled, ringent, two-lipped. *Upper lip* very ſhort, concave, emarginated; *lower lip* upright, three-cleft: the middle one rather larger.

STAM. *Filaments* four, twin: the two ſuperior ones ſimple: the two inferior aſcending: with a terminal, upright tooth. *Anthers* twin: the inferior ones ſublateral.

PIST. *Germ* ovate. *Style* filiform. *Stigma* emarginated.

PER. *Capſule* oval, one-celled, two-valved.

SEEDS numerous. *Receptacle* cylindric.

ESSENTIAL CHARACTER.

Cal. five-parted. *Cor.* ringent, with the upper lip very ſhort. *Stam.* the two lower with a terminating tooth and a ſublateral anther. *Capſ.* one-celled.

Leaves petioled ovate-roundish subserrate, stem creeping.
[3. Lindernia japonica.
Lin. syst. 567. *Thunb. jap.* 253.
Leaves obovate toothed, the lowest petioled.

DESCRIPTIONS, *&c.*

1. Root annual. Stem smooth, square, brittle, sometimes branched and putting forth runners. Leaves small, slightly crenate, like those of Anagallis, opposite. Flowers axillary, solitary, on a long slender peduncle. Calyx cut into five acute segments almost to the bottom. Corolla pale blue [a].

Native of Virginia, in watery and boggy places, flowering in july and auguſt. Hence it has migrated into Europe, and is now found in like ſituations in Alſace and Piedmont.

2. This alſo is an annual plant, a native of Hiſpaniola[b]. Mr. Miller's deſcription has been already given under *Erinus procumbens*. It muſt have been cultivated by him before 1733, the year of Dr. Houſtoun's death.

3. Root annual. Stem herbaceous, branched, weak: branches alternate, ſomewhat villoſe, from an inch to a ſpan in length. Root-leaves very many, petioled; ſtem-leaves few, ſeſſile; all obovate, blunt ſcarce apparently villoſe, unguicular. Petioles the length of the leaves. Flowers at the ends of the branches, in racemes. A very minute bracte under the peduncles. Corolla rufeſcent. Capſule ovate, blunt, twin, ſmooth.

Native of Japan [c].

N. major, rigidioribus & rarius crenatis foliis. flore purpureo gemello. *Pluk. alm.* 264.

DESCRIPTION, *&c.*

1. Root perennial, fibrous. Stems filiform, from three to ſix feet long, looſe, creeping, round, perennial, ferruginous, with a few white hairs ſcattered over them. Leaves oppoſite, roundiſh-ovate, ſpreading, attenuated into the petioles, with two or three ſerratures on each ſide, having a few upright hairs on the upper ſurface, and only on the midrib in the lower. Branches alternate, ſimple, upright, with ſix or eight leaves on them. Pedunculs terminating the older branches, ſolitary, a finger's length, upright, having different hairs ſcattered over them; ſome very minute, reflex, pellucid, others ſpreading, ſecreting a glutinous juice. Univerſal umbel biſid, with diſtant rays: partial one-flowered, horizontal. Univerſal involucre two-leaved, upright, awl-ſhaped very ſhort: partial the ſame. Perianth of the fruit ovate, a little leſs than the germ, ciliate, the cilias pellucid, bent outwards; it has ſhort hairs ſcattered all over it, terminated by a yellow globular gland. Germ ovate, with glandular hairs. Perianth of the flower five-parted, upright, ciliare with pale hairs, and having glandular hairs. Perianth of the flower five-parted, upright, ciliate with pale hairs, and having glandular hairs ſcattered about it; the calycine ſegments lanceolate-awl-ſhaped. Corolla turbinate, three times as long as the calyx, ſmooth and white on the outſide, having a few hairs ſcattered over it within, with blood-red veins within the cavity, which are yellow on the lower ſide. Stigma hiſpid.

The ſmell of the flowers approaches to that of Ulmaria or Meadow-ſweet, and is ſo ſtrong during the night as to diſcover this little plant at a conſiderable diſtance.

In Sweden, where the plant is common, an infuſion of the leaves in milk is employed in the rheumatiſm. In Norway, they cure the itch with a decoction of it. And in Oſtrobothnia they apply it in a cataplaſm or by fomentation to diſorders of the feet in ſheep [d].

Native of Sweden, Norway, Switzerland, Sileſia, Italy, Ruſſia, Siberia, Canada, in large foreſts and woods, eſpecially where moſs abounds; and flowers in june. It was introduced here in 1762, by Mr. Andrew Kallſtroem [e]. I ſuggeſted ſo long ſince as the year 1763, that it was probably a native of Ireland, but I do not know that the ſuggeſtion has been verified; it has however been at length detected in Scotland, in an old fir wood at Mearns near Aberdeen, by Profeſſor James Beattie, junior, of the Mareſchal College there [f].

LINOCARPUM. See *Linum.*

LINOCIERA. (*So named by Swartz from Geofroy Linocier, Phyſician at Tournon in the Vivarais: author of* L'Hiſtoire des Plantes. Par. 1584. 12°.)

[a] Clayton in Gron. virg. [b] Swartz. [c] Thunberg. [d] Linn. faec. [e] Hort. kew. [f] Linn. tranſ. v. 3. 335.

Lin. gen. Schreb. n. 1709. *p.* 784.
Thouinia. *Swartz prodr.* 14.
Class. 2. 1. Diandria Monogynia.

GENERIC CHARACTER.

CAL. *Perianth* very small, four-toothed, obtuse, permanent.
COR. *Petals* four, equal, linear, channelled, upright, spreading at top, many times longer than the calyx.
STAM. *Filaments* two; very short, rather broad. *Anthers* linear, two-furrowed, length of the corolla, upright, each adhering slightly to the other side of the two petals.
PIST. *Germ* superior, ovate, four-cornered. *Style* short. *Stigma* oblong, two-cleft.
PER. *Berry* ovate, sharp-pointed, two-celled.
SEEDS solitary, oblong.

ESSENTIAL CHARACTER.

Cal. four-toothed. *Cor.* four-petalled. *Anthers* connecting two opposite petals at the base. *Berry* two-celled.

Dr. Smith suggests, that by examining the fruit in an early state, it will be found that Linociera of Schreber is not distinct from Chionanthus[*].

Thouinia nutans of the Supplement is Chionanthus zeylanica. *Lin. spec.* &c.

Swartz has Thouinia ligustrina, a West Indian plant, belonging to this genus: and therefore probably a Chionanthus.

Dr. Smith has given the name of Thouinia to a very different plant.

LINOPHYLLUM. See *Thesium.*
LINOSYRIS. See *Corysocoma.*]
LINUM. (*Λινον of Dioscorides, Theophrastus*, &c.)

DESCRIPTIONS, *&c.*

The numerous ſpecies of Flax are chiefly herbaceous, ſome however are ſuffruticoſe or woody at bottom, one or two are ſhrubby, and one arboreous. In moſt the leaves are alternate (one to nineteen), in fewer oppoſite (twenty to twenty-five), generally lanceolate or linear. Flowers ſolitary, axillary or ſometimes but ſeldom oppoſite to the leaves*. Corolla commonly blue, fading ſometimes to white, but in ſome ſpecies yellow (10 and 15, &c.) red in n. 4, 8.

The genus belongs rather to the natural order of *Gerania*, than of Caryophylleæ, where Juſſieu has placed it; and the accurate and learned author himſelf confeſſes that it is diſtinct from the latter order.

1. Root annual, ſimple, fibrous, pale brown. Stem upright, eighteen inches, two feet and even more in height, round, ſmooth, leafy, branched only at top. Leaves ſeſſile, growing cloſe together, almoſt upright, perfectly entire. Flowers large, growing in a panicle, on round ſmooth pedunceles. Calycine leaflets ovate, keeled, with a membranous edge, when magnified appearing to be fringed with hairs. Petals wedge-ſhaped, deciduous, ſky-blue, ſtreaked with deeper-coloured lines; white at the claws, and ſomewhat gnawed at the

* Juſſieu.

tip. Filaments dilated at the base, and slightly united there. Anthers at first oblong, but finally sagittate, incumbent, blue. Germ ovate, shining. Styles somewhat club-shaped or thicker towards the top, blue, slightly cohering at the base [b].

This valuable plant is supposed to have been derived originally from those parts of Egypt which are exposed to the inundations of the Nile [c]. In the earliest record we have (Exodus ix. 31.) Flax is mentioned as a plant cultivated in that country; for which reason antiquaries have been surprised to find the vestments of mummies made of cotton. It is highly probable however that mankind made thread of cotton, before the use of Flax was discovered; the former being produced in a state ready for spinning, whereas the latter requires a long process before it can be brought to that state.

It is difficult, or perhaps impossible to determine when the culture of Flax was first introduced into this country. In the simplicity of former times, when families provided within themselves most of the necessaries and conveniencies of life, every garden supplied a proper quantity of hemp and flax. The macerating or steeping, necessary to separate the fibres by rotting the rest of the stalk, was found to render water so offensive, that by the 33d of Henry VIII. it was enacted, that no person should water any Hemp or Flax in any river or other stream, or in any common pond where beasts are used to be watered, under the penalty of twenty shillings. The growth of Hemp and Flax has lately been encouraged by a premium, under an act of parliament.

Flax is now found wild in many parts of Europe, in corn fields. In England it is doubtful perhaps whether it be aboriginal, though it is said to be very common in the western counties, not only in corn fields, but in pastures and on downs. It flowers in june and july [d].

The seeds of Flax (lin-seed) yield by expression only, a large proportion of oil, which is an excellent pectoral, as is likewise the mucilaginous infusion. They make an easy and useful poultice in cases of external inflammation, and they are the food of several small birds. After the oil is expressed, the remaining farinaceous part, called oil-cake, is given to oxen, who soon grow fat upon it. The oil itself differs in several respects from other expressed oils: it does not congeal in winter, nor does it form a solid soap with fixed alkaline salts, and it acts more powerfully as a menstruum upon sulphureous bodies. When heat is applied during the expression it gets a yellowish colour, and a peculiar smell. In this state it is used by painters and varnishers. It is well known that the fibres of the stem are manufactured into linnen, and that this linnen, when worn to rags, is made into paper [e].]

Mr. Miller remarks, that although the plants of Flax when crouded together in cultivation, rise only a foot and half in height, with a slender unbranched stalk; yet when they are allowed room will rise more than two feet high, and put out two or three side branches towards the top, especially in a good soil.

He makes a distinct species of the dwarf variety, because it has stronger and shorter stalks branching out more, the leaves broader, the flowers larger with the petals indented at the extremity, the seed-vessels much larger, and the peduncles longer.

[The wild differs no otherwise from the cultivated plant than most others do.

Flax in German is *Flacks* or *Lein*. In Dutch, *Vlasch*. In Danish, *Hor* or *Harr*. In Norwegian, *Lin*. In Swedish, *Lin*. In French, *Lin*. In Italian and Spanish, *Lino*. In Portugueze, *Linho*. In Russian, Polish and all the languages from the Sclavonian, *Len* or *Lan*. All the European languages, except the Danish, use *Lin*, when they speak of the seed.]

2. Mr. Miller thus describes the wild perennial Flax. From its perennial root arise three or four inclining stalks, having short narrow leaves towards their base, but scarcely any about the top. The flowers are produced at the ends of the stalks, sitting very close; they are blue, and about the size of the cultivated sort, and are succeeded by pretty large round seed-vessels, ending in acute points. It flowers about the same time as the preceding, but the roots will continue four or five years.

[The calycine leaflets are oval, hollow, with a short bluntish point at the end, not fringed or hairy, marked with five lines [f]. Its strong and knobbed root produces a multitude of slender stems, about a foot long, spreading in every direction, but more or less curved upwards. The flowers appear from june to august; they are of a delicate texture, and very elegant blue colour [g].

Ray mentions two varieties, one upright, with a larger flower and head: the other procumbent, with a smaller flower and head. He thought them to be only varieties, and Mr. Hudson asserts that he has gathered both from the same root; adding, that in the latter the stamens are shorter; in the former, longer than the styles.

Native of Cambridgeshire, Norfolk, Suffolk, Northamptonshire, on calcareous pastures.

β. Mr. Miller distinguishes the upright Siberian plant.] The stems of this are strong, in number according to the size of the root, in height from three to five feet according to the soil; they divide into several branches at top. Leaves narrow-lanceolate, not much more than an inch long, and an eighth of an inch broad, of a deep green, ending in acute points. The flowers form a kind of umbel at the ends of the branches; the stalks rising nearly of the same height. The flowers are large and of a fine blue; appear in june, and are succeeded by obtuse seed-vessels, ripening in september.

[These are thus described by the accurate Gærtner. Capsule the size of a pea, spherical, striated, pale straw-colour, ten-celled, ten-valved. Valves crustaceous, with a groove on the back, opening at top, and connected by means of the partitions; which are membranaceous, folded or doubled, with their laminæ parted on the outside, and so inserted into the margins of the valves, that when these open the others unfold like the leather of a pair of bellows. Receptacle none, but the seeds are fixed to the central margin of the partitions. Seed solitary, ovate, mucronate at top, compressed, dark-coloured, shining, with a minute oblong navel below the tip. The structure of the partition in the capsule of Linum, is distinct from all others as far as we know [h].]

Mr. Miller affirms that Siberian Flax always has more branching stalks, longer and broader leaves, larger flowers, and much larger blunter seed-vessels than our English perennial Flax. He also recommends the cultivating it for use, being perennial, earlier, more productive, and yielding a stronger, though not so fine a thread.

3. Native of New Zealand. In Queen Charlotte's Sound.

4. Root woody, perennial. Leaves with hairs as long as the leaves themselves, acuminate, five-nerved. Corolla flesh-coloured, with lines of a blood-red colour [i]. Ray found it near Augsbourg. It has also been seen near Ingolstadt, in the mountains near Bologna, &c. The stalk is glutinous or clammy, whence its name. Allione asserts that it differs in nothing from the next species.

5. Root woody, perennial. Stems round, simple, hairy, from a foot to two feet in height, often smooth at bottom, leafy all over, upright, branching at top into flowering corymbs. Leaves lanceolate or ovate, acuminate, sessile, alternate except a few at the ends of the branches, which are opposite, hairy especially at the edge and on the dorsal nerves, but sometimes almost smooth. Flowers on very short peduncles, not from the axils, but a little higher, and also from the division of the branches. Calycine leaflets lanceolate, half the length of the corolla. Petals blue marked with lines, firmly embracing each other at the lower part, though not united at the base, representing even after they are fallen a monopetalous funnel-form flower.

[b] Curtis. [c] Withering. [d] Curtis. [e] Withering.

[f] Stokes in Withering. [g] Engl. bot. Raii hist. [h] Gærtn. fruct.

Anthers pale. No rudiments of barren ſtamens. Germ hirſute. Capſule roundiſh, ſmooth, ten-celled, five-valved. Scopoli attributes to his L. hirſutum four ſtyles, and a four-celled capſule. Jacquin is of opinion that L. ſylveſtre of the ſame author is the ſame with L. viſcoſum of Linneus. This is diſtinguiſhed from that by the hairs on the edge of the leaves, as well as the ſurface being quite ſimple, and not with glandular heads at top. The leaves of L. hirſutum are ſometimes very plainly three-nerved, and ſometimes the nerves ſcarcely appear. Cluſius's ſecond L. ſylveſtre latifolium does not ſeem to be different from this, notwithſtanding the colour, which varies in this ſpecies, on one hand of a deeper blue, and on the other almoſt white [a].

Linneus obſerves, that this bears a great reſemblance to L. nodiflorum, but that the ſtem is round, the leaves ciliate or hirſute, and broader, the ſtem-leaves alternate, but the branch-leaves oppoſite, the flowers ſeſſile, alternate, the calyxes leafy and long, the branch or floral leaves and the calyxes ciliate with very ſhort glandular briſtles, eſpecially towards the top.

Native of Auſtria, and Hungary.]

6. Stem from a foot to eighteen inches high, branching out almoſt to the bottom into many long ſlender branches. Flowers at the ends of the branches, in a ſort of umbel, ſmaller than thoſe of the firſt ſort, and of a pale blue colour. The ſeed-veſſels are much ſmaller, and not ſo round.

[The root is perennial. Calyxes large, lanceolate, membranaceous at the ſides, moſt exquiſitely acuminate at top, and having a ſort of awl-ſhaped dagger-point [b].

Native of the South of France, Switzerland, Italy. It flowers from may to july. Cultivated by Mr. Miller in 1759 [c].

7. Stem a foot high, round, woody, branched from the baſe. Leaves dark green, ending in a very ſharp dagger-point. Flowers in a ſort of umbel, large, blue [d].

Native of the South of Europe. Introduced in 1778 by Caſimir Gomez Ortega, M. D. It flowers in july [e].

8. Root perennial, woody, branching. Stems aſcending at the baſe, and then erect, round, ſmooth, annual, from ſix inches to a foot in height, branched at top, and there leſs cloſely ſet with leaves. Leaves narrow, acuminate, firm, ſhining, moſtly ſhorter than an inch, ſeſſile, ciliate with whitiſh ſpinules bowing upwards, when examined with a glaſs. Flowers in a ſort of panicle, peduncled. Calyx ciliate at the edges. Petals roſe-coloured, purple or white, nearly twice as long as the calyx. Filaments broader at bottom, and no rudiments of barren ones. Capſules roundiſh-acuminate, ſmooth [f].

Native of the South of Europe.

9. This is moſt nearly allied to L. uſitatiſſimum in all its parts, except in having a woody perennial root producing many ſtems; it differs alſo at firſt ſight in having ſmaller paler flowers. The leaves have three, ſometimes five nerves, their edges entire and ſmooth. Calyx-leaves ſmooth, elliptical, with a ſharp point; in the flowering ſtate ſcarcely more than one nerve is viſible, but as the fruit ripens the calyx becomes diſtinctly three-nerved. Petals entire or ſlightly notched. Valves of the capſules diſtinctly ten, cohering by their inflexed margins, which make the partitions of the ten cells.

The preceding, with which Linneus confounded this has a very long-pointed calyx, with glandular ſerratures, and leaves which have rough edges and only a central nerve. L. perenne is ſufficiently diſtinguiſhable by its more obtuſe five-nerved calyx, and more capitate ſtigmas [g].

Native of Cornwall and Devonſhire, in dry ſandy paſtures, eſpecially near the ſea. Darſham in Suffolk. Minſter in the iſle of Shepey, Beacon-hill and Deal in Kent. By Pett near Haſtings.

10. Root annual. Flowers yellow. Commonly five, but ſometimes only three piſtils. Native of the South of France. Introduced in 1777, by Monſ. Thouin. It flowers in july [h].

11. Root perennial. Stems herbaceous, round, almoſt upright, glaucous, branched at top, a foot high or more. Leaves covering the whole ſtem and branches, oval-oblong, ſharpiſh, glaucous, ſeſſile, upright, quite entire, half an inch long. Peduncles commonly oppoſite to a leaf, upright, one-flowered. Petals yellow. Germ ſmooth. Styles yellow, ending in hirſute ſtigmas. Capſules roundiſh, acute, the ſize of the calyx, ſmooth, five-toothed at top, five-grooved, ten-celled, five-valved. Seeds ovate, compreſſed, browniſh-yellow [i]. Linneus obſerves, that it is allied to the preceding. Native of the South of Europe and the Levant. Cultivated in 1596, by Gerarde. It flowers in july and auguſt [k].

12. Root perennial, branched. Stems herbaceous, ſimple, half a foot or more in length, round, very leafy, procumbent or aſcending, many-flowered and often divided. Leaves quite entire, ſeſſile, the upper ones almoſt upright, the next ſpreading; the lower ones imbricately reflex. Flowers peduncled, large. Petals pale blue, three times as long as the calyx. Capſule roundiſh, ſmooth, containing ten, ovate, ſhining, compreſſed, blackiſh ſeeds [l]. Native of Auſtria, Piedmont, Dauphiné, Sileſia.—Introduced in 1775, by Monſ. Thouin [m].

13. Root perennial, woody. Stems herbaceous, annual, from ſix to eighteen inches long, round, ſimple or divided only into ſhort branches at top, ſometimes for the moſt part procumbent, ſometimes more upright. Leaves ſubſeſſile, quite entire, ſublanceolate-linear, ſmooth. Peduncles one-flowered, filiform, axillary, ſolitary, pendulous before the flowers open, and when in fruit. Petals wide, purpliſh blue or violet with darker lines and a yellow claw, quite entire, reſembling thoſe of the firſt ſort. Filaments and ſtyles blue. Anthers pale. Stigmas greeniſh yellow, headed. Piſtils bent back beyond the ſtamens. Seeds brown. The whole plant is ſmooth. The leaves vary in width [n]. Native of Auſtria and the Palatinate. Introduced in 1775, by Monſ. Thouin. It flowers in june and july [o].

14. Stem filiform, a foot high, panicled. Flowers on very ſhort peduncles. Corollas yellow. Capſules globular, awnleſs. Native of Virginia and Penſylvania [p].

15. Root perennial, woody. Stems herbaceous, upright, from ſix to eighteen inches high, ſmooth, rendered angular by membranes which ſeem to ariſe from the ſides and middle of the leaves. Leaves ſeſſile, narrow-lanceolate, acute, quite entire, ſmooth, thickiſh, about an inch and half in length, having a dot or ſeſſile gland of a bay colour on each ſide at the baſe, as in L. campanulatum. Flowers elegant, upright, on ſhort peduncles, at the end of the branches, and at the diviſions of them. Calycine leaflets acuminate, whitely ſerrate-ſpiny when examined by a magnifier. Petals three times as long as the calyx, yellow, ſtriate-veined, wide and very blunt. Filaments yellow, upright; five twice as long as the calyx with yellow anthers and five others very ſhort and barren, ſtanding alternate with the fertile ones. Styles yellow. Capſule roundiſh, ſharp, browniſh [q].

Native of Auſtria. Introduced by Mr. Curtis about the year 1794, from ſeeds ſent him by Monſ. Daval of Orbe in Switzerland. The flowers open moſt in a morning when the ſun ſhines, and continue in ſucceſſion during june, july, and part of auguſt [r].]

16. This is an annual plant, with an upright ſtalk near a foot and half high. The leaves are about the ſame length with thoſe of common Flax, but a little broader. The ſtalks divide towards the top into ſeveral branches, each ſuſtaining two or three yellow flowers; which appear in july; but the ſeeds ſeldom ripen in England.

[Linneus remarks, that it is a ſtiff, corymbed plant; that the leaves are rugged about the edge, the calyxes awl-ſhaped, twice as long as the fruit. Native of the

South

South of France, Spain, and Sicily. Ray found it near Montpeſſier and in Sicily. Cultivated by Mr. Miller in 1759.]

17. This has a ſhrubby ſtalk a foot high, ſending out ſeveral branches. Leaves very narrow, coming out in cluſters, but on the flowering-branches broader and longer. Flowers at the ends of the branches, erect on long ſlender peduncles. Calyxes acute-pointed. Petals large, entire, white, but before the flowers open pale yellow. They appear in July, but the ſeeds ſeldom ripen in England. The flowering ſtalks decay in the autumn, but the lower ſhrubby part, continues with the other branches all the year.

[Native of Spain, about Aranjuez, but common in the kingdom of Valencia. Mr. Miller ſays he had the ſeeds of his L. fruticoſum from Ortega at Madrid. It ſeems to be the ſame with the ſuffruticoſum of Linneus, and therefore I have given his deſcription, not a word of it being ſaid by Linneus or Quer, though he had ſeen it.

According to the Kew Catalogue it was introduced in 1787, by Monſ. Thouin. But if Mr. Miller's plant be the ſame, he cultivated it in 1759.

18. This beautiful ſpecies forms, if not a tree, as its name imports, a ſhrub of the height of ſeveral feet. It begins to flower in march, and continues flowering to the cloſe of ſummer; but has not yet produced ſeeds in England[a]. Native of the iſland of Candia. Introduced in 1788, by John Sibthorp, M. D[b].

19. Stems ſimple, a fingers length, angular, commonly terminated by three, large, peduncled flowers. Calyxes lanceolate, acuminate. Native of the South of France and Ruſſia[c].

20. Stem ſuffruticoſe, ſtiff, a foot high, round, with ſimple branches. Leaves ſeſſile, upright, even, generally ſhorter than the internodes. Flowers in a terminating umbel, which is four or five-cleft with dichotomous rays. Petals yellow with villoſe claws, and turning tawny. Calyx acuminate, rugged at the edge[d].

Native of Africa. Introduced in 1771, by Monſ. Richard. It flowers in june and july[e].

21. Stem angular, even, biſid or trifid. The leaves have an ovate brown gland at the baſe on each ſide: the ſtem-leaves are alternate lanceolate and even; the branch-leaves oppoſite and narrower. Calyx linear, leafy. Corolla yellow. Capſule globular, acuminate[f].] Root perennial. Stalks two or three, ſlender, ſtiff, dividing at top into two or three ſlender branches. The flowers came out ſingly at the joints, and ſit cloſe to the ſtalks. The calyxes are cut into five ſlender ſegments, longer than the petals.

[Native of Italy. Cultivated by Mr. Miller in 1759.

22. Root annual, very ſmall. Stems ſeveral, from three to nine inches high, aſcending at the baſe then upright, round, ſmooth, branching at top into a forked, leafy, ſlender-ſtalked panicle. Leaves ſeſſile, upright, blunt with a ſlight point, entire, glaucous beneath. The whole herb is ſmooth. When the paniele begins to branch off, its lower branches, as well as the leaves that accompany them, are alternate. Flowers terminating, ſolitary, pendulous before they open, then erect, not unlike thoſe of an Arenaria. Calyx-leaves ovate-lanceolate, pointed, ſerrate, with a ſolitary nerve; the edges fringed with minute glands on foot-ſtalks. Petals white, obovate, pointed, twice the length of the calyx, ſpreading, ſlightly united at the baſe, having three ribs and yellow claws. Filaments united, forming a bag which incloſes the lower half of the germ. Stigmas capitate. Capſule ten-valved, but before it is quite ripe, cohering in pairs by means of the permanent ſtyles. Seeds yellow, ſhining[g].

It ſometimes varies with four ſtamens, and four ſtyles[h].

Native of moſt parts of Europe. This ſmall delicate ſpecies of Flax, called alſo in ſome places Mill-mountain, is very common throughout England in dry and hilly paſtures, and flowers from the end of may to auguſt.

[a] Cart. magaz. [b] Hort. kew. [c] Linn. [d] Ibid. [e] Hort. kew. [f] Linn. [g] Engl. bot. & Curt. lond. [h] Wiggers.

Gerarde celebrates this little plant as a purge. His receipt is a handful of the herb infuſed in a pint of warm white wine all night, and taken in the morning. Lewis preſcribes an infuſion in water or whey of a handful of the freſh leaves, or a dram in ſubſtance of them dried. Dr. Withering recommends an infuſion of two drams or more of the dried herb, as an excellent purge in many obſtinate rheumatiſms: and adds that it frequently acts as a diuretic.

23. Root annual. Stem upright, an inch high or more, very much branched and dichotomous, round, filiform, ſmooth. Leaves ſeſſile, ovate, acuminate, quite entire, bright green, ſmooth, a line and half long and a line broad. Flowers upright, ſolitary, in little bundles at the ends of the branches, the lower ones on peduncles more than two lines in length: they are ſmall, and white. Calyx four-leaved, the length of the corolla. Petals four, upright, ſmall, roundiſh, blunt. Stamens and ſtyles four[a]. Hence ſome have ſeparated this ſpecies from the reſt, and have made it a ſeparate genus under its own name of Radiola.

Native of many parts of Europe. With us on moiſt ſandy heaths, flowering in july and auguſt. Its Engliſh names are *All-ſeed* and *leaſt Rupture-wort*.

24. From a thick woody root this puts up ſeveral ſtems, ſix inches high or more, ſlender, upright, with leaves in fours at intervals, as in the ſtellate plants, dividing at top into branches, which ſupport large blue flowers[b].

Native of the Cape of Good Hope.

25. This is an annual plant, and does not exceed a foot in height. Stems round, branched. Leaves in whorls, upright, acute, ſcarcely an inch in length. Flowers violet or blue-gray. Capſule round, pointed. Seeds olive-coloured[c]. The calyxes and upper leaves are villoſe.

Native of Italy[d]: near Rome.

The ſpecies may be diſtinguiſhed at one view from the following table.

Leaves alternate.
1 to 19. Lanceolate. 1. 2. 4. 6. 11. 14. 15. 16.

- Ovate-acuminate. Corolla white. 23.
- In fours. Corolla blue. 24.
- In whorls. Corolla blue. 25.]

PROPAGATION AND CULTURE.

1. Flax ſhould be cultivated upon a rich ſoil, that has not been ploughed for ſeveral years, upon which it always makes the beſt improvement; but as it draws greatly from the ſoil, it ſhould not be ſown two years together upon the ſame ground, nor in leſs than after five or ſix years interval.

The ground ſhould be as clean from weeds as poſſible: in order to have it ſo, it ſhould be fallowed two winters and one ſummer, obſerving to harrow the ground well between each ploughing, particularly in ſummer, to deſtroy the young weeds ſoon after they appear: this will alſo break the clods, and ſeparate the parts

[a] Pollich. [b] Ray ſuppl. [c] Barrelier. [d] Linn.

ſo, that they will fall to pieces on being ſtirred. If the land ſhould require dung, that ſhould not be laid on till the laſt ploughing, when it muſt be buried in the ground: but this dung ſhould be clear from ſeeds of weeds, which it may be by laying it in a heap and fermenting it well. Juſt before the ſeaſon for ſowing the ſeed the land muſt be well ploughed, and laid flat and even. The ſeeds ſhould be ſown at the end of march or the beginninnig of april, when the weather is mild and warm.

The common way is to ſow the ſeed broadcaſt, and to allow from two to three buſhels of ſeed to an acre: but from many repeated trials I have found it a much better method to ſow the ſeeds in drills, at about ten inches diſtance from each other, by which half the quantity of ſeed uſually ſown will produce a greater crop; and when the Flax is thus ſown, the ground may be eaſily hoed to deſtroy the weeds: if this operation be twice repeated in dry weather, it will keep the ground clean till the Flax is ripe: this may be done at half the expenſe which hand-weeding will coſt, and will not tread down the plants nor harden the ground, which by the other method is always done; and it is abſolutely neceſſary to keep the Flax clean from weeds, otherwiſe they will overbear and ſpoil the crop.

Some recommend feeding ſheep with the Flax, when it is a good height; and affirm that they will eat the weeds and graſs, and do the Flax good, and if they ſhould beat it down, that it will riſe again with the next rain. But this is a very wrong practice, for if the ſheep gnaw the Flax, it will ſhoot up very weak, and never come to half the ſize it would have done, if it had not been cropped: and if the ſheep like the crop better than the weeds, they will devour that, and leave the weeds untouched.

Towards the end of auguſt or at the begi nning of ſeptember the Flax will begin to ripen, and it muſt not ſtand to be over ripe: it muſt therefore be pulled up as ſoon as the heads begin to change brown and hang downwards, otherwiſe the ſeeds will ſoon ſcatter and be loſt; ſo that the pluckers muſt be nimble, in tying up the plants in handfuls, and ſetting them upright, till they are dry enough to be houſed. If the Flax be pulled when it firſt begins to flower, the thread will be whiter, but then the ſeed will be loſt: the thread however will be ſtronger when Flax is left till the ſeed is ripe, provided it does not ſtand too long; but the colour of it will not be ſo good.

The Siberian perennial Flax (n. 2) has been tried, and anſwers very well for making common ſtrong linnen, but the thread is not ſo fine or white as that which is produced from the common ſort; but as the roots of this will continue many years, it will require little other culture but to keep it clean from weeds, which cannot well be done, unleſs the ſeeds be ſown in drills, that the ground may be conſtantly kept hoed to deſtroy the weeds when young. This ſort muſt have the ſtalks cut off cloſe to the ground when ripe, and then managed in the ſame way as the common ſort: but it ſeldom produces more than three crops that will pay for ſtanding.

Mr. Miller mentions another ſort with a biennial root, which he therefore names L. bienne. He received it from Iſtria, and ſays that it produced the fineſt thread of all the ſorts which he had tried. It grows taller than the common Flax, and in gardens lives through the winter without receiving the leaſt injury from froſt. Mr. Miller gave a parcel of the ſtalks of this, with the Spaniſh and Siberian perennial ſorts, to a perſon well ſkilled in watering, breaking and dreſſing Flax, who having prepared them, aſſured him, that the Iſtrian Flax was by much the fineſt of the three, and was in goodneſs preferable to any he had ſeen.

The other ſorts are chiefly preſerved in Botanic gardens. L. catharticum (n. 22.) or purging Flax, is one of thoſe plants which refuſe culture; the ſeeds whether ſown in ſpring or autumn will ſeldom come up.

[Several of the ſpecies are handſome plants. The Siberian Flax (n. 2.) is now very commonly found among hardy perennials in the borders of large flower-gardens and plantations, and is eaſily increaſed either by ſeeds or parting the roots.

L. flavum (n. 15.) bears large yellow flowers, and is a hardy perennial. It appears to be eaſy of culture, and ſucceeds beſt in a ſoil moderately ſtiff and moiſt. The ſeeds vegetate freely, and it may be increaſed either by parting the roots in autumn, or by cuttings of the young ſhoots.

Some of the ſorts (n. 6. 17. 18. 20.) require the protection of a Greenhouſe. N. 17, 18. 20. may be increaſed by cuttings, but not without ſome difficulty. They ſeldom or ever ripen their ſeeds in this country.

Old paſtures, eſpecially on land formed from the ouze or ſediment of great rivers, are the beſt adapted to the growth of Flax. In Reedneſs, a tract of land in the county of York, on the ſouth ſide of the river Ouze, near its junction with the Trent, they frequently plough their old paſtures, when the herbage begins to fail, and adopt the following courſe of crops, viz. 1. Flax. 2. Rape or Cole. 3. Flax: and if the ground ſtill continue too rank for Corn, they add 4. Rape. 5. Flax. 6. Oats.

When they break up the paſture, they plough the ſward in december, about three inches deep; in this ſtate it receives the winter's froſt, and without any more preparation they ſow the ſeed (linſeed) two buſhels on an acre, the ſecond or third week in april, if the weather permit; or if not, as ſoon after as poſſible; and with light ſhort-tined harrows, that will not drag the ſod, they harrow it pretty much to mould. They keep the crop as free as poſſible from weeds, for which purpoſe it is hand-weeded once or twice, in dry weather, before, and not after the Flax is four inches high; from that time it will out-grow and nearly ſmother every weed, and will be ready for pulling by hand, the ſecond, third or fourth week in july, according to the ſoil and ſeaſon: but if it be intended for ſeed, it will require about a fortnight more. It is next tied into ſheaves of about three inches diameter, with bands made of part of the Flax; and whilſt the pulling and tying are going on, in dry weather, if poſſible, a team is employed in carrying it to the pits or ponds, which are previouſly well cleanſed: here it is laid cloſe and trod, one layer of ſheaves upon another, until the man who treads it ſtands about mid-leg deep in water; the Flax is then covered with ſods, earth, &c. ſufficient to keep it entirely under water; a briſk fermentation enſues, and the pit ſtinks abominably; in this ſtate it receives an additional treading, every night and morning, for about four days; when a ſheaf is taken out of the pit, untied, and ſpread on the ground to dry; when dry, it is tried by rubbing between the fingers, to ſee if the bun (hecks or ſpongy part of the ſtalk) be ſufficiently brittle to ſeparate readily from the Flax (or fibres;) if not, they try another ſheaf the day following, by which time it is uſually raited (retted or rotted) enough; though, if the growing ſeaſon has been more than uſually wet, the Flax will be raited a day or two ſooner: if needful, they try it again on the ſixth and even the ſeventh day. As ſoon as it is diſcovered to be ſufficiently raited, it is all taken out of the pit, and every ſheaf being untied, is ſpread on clean graſs land. Here it lies to dry from five to ſeven days, unleſs a conſiderable ſhower fall ſooner; when it is to be turned, that both ſides may be bleached alike; and it is ſometimes turned a ſecond or third time. The bun is frequently tried, to ſee if it be brittle, and part readily from the Flax. They are alſo particularly attentive to obtain their Flax of a lead colour, which complexion they value even more than the rottenneſs of the bun. When bleached ſufficiently and perfectly dry, it is tied into ſheaves, five or ſix times as large as the former, and carted into ſheds or ricks; whence it is ſwingled and tied up for ſale by profeſſional labourers. The crop is from twenty-five to ſeventy ſtone on an acre.

The account of an acre may ſtand nearly thus,

The average crop forty ſtone, at 9*d.* the medium price, and the bounty 4*d.* together	18	13	4
Every expenſe about 6*l.* with rent, taxes, aſſeſſments and tithes, about 2*l.* 13*s.* 4*d.*	8	13	4
Remains Profit £.	10	0	0

This profit is very great, but what makes the crop of Flax ſtill more valuable, is the additional employment it gives to the poor in weeding, pulling and tying, management of the pit, drying and ſwingling to the amount of four or five pounds an acre; the article of ſwingling alone, might go a great way towards giving employment to the poor in country parithes during the dead months of winter. After the crop is off, the ground is cleared of weeds and graſs, and as ſoon as convenient is ploughed an inch or two deeper, and rape ſeed from half a peck to a peck on the acre, according to the richneſs of the ſoil is ſown, from a week before to a week after michelmas. The ſeed loft in reaping and getting the Rape produces a crop of green food for ſheep, which is fed off early enough to prepare the ground for a ſecond crop of flax. If a third crop be taken after Oats, when that is off, a judicious mixture of graſs ſeeds is ſown, and the ground returns to meadow and paſture again".

The following is the expenſe and profit of five acres of Flax raiſed in Shropſhire.

		£.	s.	d.
Rent, including tithe	—	13	10	0
Seed	—	3	3	0
Weeding, drawing, and ſticking up		2	0	0
Binding and carriage	—	0	12	0
Threſhing and winnowing	—	2	2	0
Spreading, gathering and carriage		1	14	3
Swingling, at 1s. per ſtone		14	1	4
		42	3	7
Produce.				
281 ſtone 5lb. at 5s.	—	70	6	3
Seed, 49 buſhels	—	13	7	0
		83	13	3
Bounty	—	4	13	9½
		88	7	0½
		42	2	7
		46	4	5½

There is no charge in the above account for ploughing and harrowing, it being uſual to give a large rent for old paſtures, by thoſe who make a buſineſs of raiſing Flax, the perſon who lets the land engaging to plough and harrow it with his team. The above crop was conſidered as a large one[1]; yet the profit is ſomewhat leſs than the above, being 9l. 4s. 10½d. per acre.

The quantity of ſeed ſown on an acre in the Iſle of Ely is two buſhels, the coſt of which is a guinea or thereabouts; an experienced man is employed to ſow the ſeed, there being few who underſtand that buſineſs. No manure is wanting, where clean or ſward land is uſed, which is generally the caſe. The ground is ploughed but once, and harrowed fine. If rich, it will bring turneps, wheat, or clover, &c. after the flax is off. The coſt is ſomewhat about 3l. an acre. The produce from twenty to fifty ſtone, according to the land. When it is fit to pull, a man ſhould be employed who knows when to put it into the dike, and when to take it out, there being much difficulty in managing that point, without ſpoiling the flax. It is ſuppoſed not to impoveriſh the land, but to improve it[2].

In Ireland, on mountain lands they prefer American flax-ſeed; upon heavy or clay-lands they ſow Riga, Dutch or Flanders ſeed: the quantity they get is more and better in quality than from the Americans, and will laſt twenty years. For fine linnens they never ſave ſeed, pulling it green; but for coarſe linens they ſave as much ſeed as they can. The produce of the flax depends on its finneſs; and the goodneſs of the linnen, on not being too much bleached.

[1] Middleton in Young's Ann. 14. 92.
[2] Harris in Young's Ann. 13. 108.
[3] Irish papers, 4. 235.

They plough their potato land or barley ſtubble once at the end of march or april, and then ſow it. They weed the Flax very carefully. They generally pull it at the end of july, or beginning of auguſt, and immediately ripple it to get the ſeeds off, and then lay it into water from ſix or ſeven to twelve days, according to the ſoftneſs of the water, trying it before they take it out. They generally lay it in bogs or pools, but reckon the bogs beſt. When they take it out, they ſpread it on meadow ground from ten to fifteen days, according to the weather; if dry it will be bad, much of it is loſt. They dry it by laying it in heaps on a hurdle fixed upon poſts, and making a fire of turf under it. As ſoft as it dries, they beat it on ſtones with a beetle, then they ſcutch it to ſeparate the heart or the *ſhoves* from the reſt. Mills are invented for this; and if they uſe theſe, they pay 12d. a ſtone for it. They next ſend it to the flax-heckler, who gives it a ſort of combing, and ſeparates it into two or three ſorts. In this ſtate it is ſaleable. The crop is from eighteen to forty-eight ſtones per acre of flax, rough after ſcutching: the medium thirty ſtones, and it ſells from 6s. 8d. to 9s. the ſtone. Much Dutch flax is imported, alſo from Riga, Konigſberg and Peterſburg.

Their Flax courſe for light and dry ſoils is 1. Turneps. 2. Flax. 3. Clover. 4. Wheat.

The Turneps ſhould be eaten on the land. The common tillage of turnep-land for barley is applicable to the Flax, which requires the land to be very fine and friable: roll in the clover ſeed in the ſame manner; and the weeding and pulling the flax will aſſiſt its growth. The flax may be ſtacked like corn, and thraſhed in the ſpring.

Their Flax courſe for ſtrong ſoils is 1. Beans. 2. Flax. 3. Clover. 4. Wheat. The bean land is prepared for the Flax, by getting off the beans as ſoon in auguſt as poſſible; ploughing the ground directly if the weather be dry, and if the ſeaſon permit giving it two more ploughings before winter, leaving the lands rounded up ſo as to ſhoot off all water, with deep and well-cleanſed furrows.

Their Flax courſe for any ſoils except very ſtrong ones, is 1. Potatoes. 2. Flax. 3. Clover. 4. Wheat. The potatoes to be managed in the common way, only upon taking them up, the land to be left till ſpring, letting no water reſt on it in winter, if it be a wetniſh ſoil. In the ſpring plough more or leſs, ſo as to inſure a fine friable ſurface to ſow the Flax in. In all theſe courſes the fallow crops, or turneps beans and potatoes muſt be kept abſolutely free from all weeds, and in looſe friable order. It is the principle of this huſbandry to baniſh fallows, but then it is neceſſary to be aſſiduous to the laſt degree in keeping theſe crops in the utmoſt perfection of management[3].

In Dorſetſhire the beſt ſeed is annually imported from Riga, it being conſidered as very material to change the ſeed. It is generally ſown broad-caſt about the middle of april, at the rate of two buſhels to an acre, upon any ſtubble, after only one ploughing, and clover-ſeed is often ſown with it. It is ripe about the end of july, or beginning of auguſt, when it is drawn by hand, by women and children, and laid in ſwaths till it is dry, then bound up in ſmall bundles, and the ſeed is beaten out in the field where it grew, by a ſtaff heavier than the common one, and the ſeed ſifted clean into a large ſheet; afterwards the ſtalk is laid on ſtubble or paſture ground, till it is completely dried; being often turned, and if the weather be wet ſet up in ſmall bundles. When it is ſufficiently dried, and fit to bark, which is called ſcutching, it goes to the flax-dreſſer, to be prepared for the manufacturer. It is always pulled up in a green ſtate, and is fit to draw, when the leaf on the ſtalk drops, and the milky juice is dried up.

The ſtalk is never thrown into water, as is the common practice of Lincolnſhire and other places, but attains its proper ſtate more gradually, by what is called dew ripening, or expoſing it to the air and dews for a long time together. From eight to twelve buſhels

[3] Young's Ireland, vol. 1. 135. and vol. 2.

of ſeed on an acre is eſteemed a good crop[a]: dry ſeaſons ſuit it beſt; and the farmers think, if it be not ſown more than once in ſix years, it does not exhauſt the land. This crop, beſides the ſeed, produces from fifty to ſixty dozen pounds weight on an acre of flax for ſpinning, worth from 4s. 6d. to 7s. the dozen. Its value is generally from eight to ten pounds an acre, including the ſeed; but it is a precarious crop, much dependant upon ſeaſons.

The land is frequently let to a middle man, called a flax-jobber, who pays the farmer four or five pounds an acre, manages the crop, finds ſeed and labour, and expects nothing from the farmer but ploughing, and the diſcharge of parochial taxes.

The inferior ſeed, not good enough to be ſown, is valuable for the oil which it yields. Two gallons may be extracted from a buſhel of ſeeds, which weighs about forty-eight pounds. The remaining hull or huſk produces the oil-cake, ſo much eſteemed for feeding cattle. Flax-ſeed is alſo uſed for the ſame purpoſe, by boiling or bruiſing, and then ſteeping it in hot water. Where malt grains can be had to mix with it, this food is of a very nourihing quality*.

The culture of Flax is very general in Perthſhire, but is not carried to a great extent in any one place. The ſoil of every brook in the Highlands, where the water runs ſlowly, and plenty of fine ſediment is depoſited, carries amazing crops of Lint. On the banks of large rivers, where the land is flooded by backwater, the Lint is generally a good crop: and Lint is raiſed ſucceſsfully, the ſecond crop, after good clover lay, which ſaves weeding; but this ought to be ſparingly practiſed, becauſe it is a bad rotation.

If perſons were at pains to preſerve the ſeed, an immenſe ſum would be ſaved annually. For this purpoſe the ſtraws may be ſtacked till ſpring: and the ſeed may then be eaſily rubbed off by a roller, without injury to the rind; the ſheaves being laid head to head during the operation. The people have the whole ſummer before them to water and dreſs their Lint. Or if this proceſs be thought tedious, or they think that they lie too long out of their money, the Lint may be rippled a few days after it is pulled; the capſules dried in the ſun, or on a kiln, and the Lint watered immediately, and dreſſed. The ſeed ought to be changed annually from one ſoil to another.

It muſt be acknowledged that this crop makes no return of manure, and impoveriſhes the ſoil to a great degree. But when it is managed with judgement, it can purchaſe manure, and bring a conſiderable profit beſides: nor does it rob the ground more than wheat, provided the land be fallowed whenever the crop is taken off. Clover and other artificial graſſes grow, when ſown with Flax, better than with any other crop[b].

In Ayrſhire, about ſeven pecks of Flax ſeed are uſually ſown upon a Scotch acre, and when the land is well pulverized and duly weeded, produces at an average twenty ſtone of 24 lb. Engliſh weight, worth about 12s. the ſtone, or 12l. per acre. Two-pence a pound is paid for ſcutching; 1d. for heckling or hatcheling; and when the Flax ſpins into forty-eight cuts per lb. it will coſt 16d. for ſpinning. One cut is equal to five ſcore threads, or turns of the reel; two cuts make one hear; twelve cuts one hank, haſp or ſkip; four hanks, or forty-eight cuts, one ſpindle.

Flax worth 1s. per lb. uſually ſpins from thirty-ſix to forty-eight cuts per pound. Tow or hards is ſold as low as 5d. Flax capable of ſpinning to ſeven ſpindles per lb. is worth 7s. Linnen cloth for home conſumption, worked in what is called a 1400 reed, coſts about 7d. a yard for weaving, and is worth 2s. 4d. or half a crown the yard.

Flax in this country is by many degrees leſs vigorous and luxuriant than in Flanders, where the fine lace and cambrics are manufactured[c].

They have a particular method of managing Flax in that country, which in French is called *Linrage*. The land is ploughed and manured for it before winter: in the beginning of march, or ſooner, according to the ſeaſon, it is deeply ploughed again: ſome days before ſowing they ſpread upon the land ſome pigeon's dung, and they cover the ſeed with a harrowing and rolling. When the Flax is four or five inches high, they weed it with the moſt ſcrupulous attention, and then build a kind of cover hanging over the little plants in the following manner. They ſtick on both ſides of the ground, bordering the ridge, ſome ſtrong wooden forks, about ſix inches high, upon which they put poles along the width of the ridge, in a direction parallel to the ground. Theſe poles are croſſed by ſmall ſticks, branches of trees, &c. ſo as to form a kind of grate full of holes, through which the plants of Flax paſs, as they grow up: by this method their ſtems have a good defence againſt wind and rain, and their roots againſt either exceſſive humidity or heat; and thus their vegetation is very much benefited. The produce is very great; and when it ſucceeds well, the crop exceeds in value the land where it grows. The culture, indeed, is very expenſive, for the requiſite wood coſts about 16l. If, however, the crop on an acre be worth 50l. and upwards, when an acre cultivated in the common way is worth no more than from 10l. to 15l., the expenſe and trouble are well paid; and the wood, when the crop is gathered, is ſtill good for ſomething*. This culture is probably adopted with a view of drawing up the Flax tall and ſlender, for the purpoſe of having the fibres finer, for the delicate fabrics of that country.

It has been ſtrongly recommended, inſtead of ſteeping the Flax in ponds or other cold water, to ſeparate the *boon* or pulp of the ſtalk from the *harle* or fibrous part, which conſtitutes the Flax, by boiling it in water. If this proceſs ſhould be found to anſwer as well as the common one, much time and labour would be ſaved, and the air and waters would not be poiſoned as they now are where Flax and Hemp are ſteeped. The Flax would alſo probably be of a finer colour; and the operation of bleaching would be ſafer, and leſs tedious. Whether the ſtrength of the thread would be improved or diminiſhed, muſt depend upon experience[d].

From the foregoing accounts, and the reſult of general experience concerning this crop, the following obſervations may be made.

1. That Flax requires a rich dry ſoil, or fat ſandy loam, particularly that which is formed from the ſediment of great rivers: and that old graſs-land of this deſcription is its moſt proper matrix. It is, however, not unfrequently, ſown on arable land, and when the ſoil is in heart, dry, friable and clean, with good ſucceſs.

2. Much depends on the ſtate of the ſoil at the time of ſowing. It ſhould neither be wet nor dry, and the ſurface ought to be made as fine as that of a garden bed. For the crop ſhould all riſe together, and the ſurface ſhould be evenly ſeeded. If the plants come up at ſeveral times, or if by accident or miſmanagement they are thin upon the ground, the crop is irreparably injured. This will be the caſe in a ſeaſon of drought, or when ſpring froſts are ſevere, or when the crop is attacked by a ſmall white fly, or when the ground being full of clods the ſeeds are not evenly diſperſed, but not being able to pierce the clods, come up in circles round them, leaving vacancies in the centre favouring their early branching; than which nothing is more detrimental to the crop; the goodneſs of it depending much on its running up with a ſingle ſtalk, for wherever it branches the fibres terminate, and they are worked off in dreſſing.

3. If the crop be intended for thread of the firſt quality, the time of pulling is when the ſeeds are formed, but if they be ſuffered to ripen, the advantage gained by the ſeed is balanced by the inferior quality of the Flax, the filaments being harſh, and the cloth made from them not taking a good colour in whitening. It is alſo a great exhauſter of the ſoil, when it ſtands for the ſeed to ripen.

* Bath papers 5. 207. Gent. magaz. and Curtis flora Londin.

4. The Flax crop interferes with harveſt, and therefore ought to be confined to rich graſs-land diſtricts, where harveſt is a ſecondary object, and where exhauſtion may be rather favourable than hurtful to ſucceeding arable crops, by checking the too great rankneſs of rich freſh-broken ground[1].

DESCRIPTIONS, *&c.*

Linneus ſeparates this genus from Borbonia, becauſe the tenth ſtamen is not deficient in this, as it is in Borbonia. Lamarck unites them. The character of the genus is taken from the firſt ſpecies. It is compoſed of Shrubs, that have the habit of Borbonia, ſmooth or villoſe. Leaves ſimple, ſeſſile, ſmooth or villoſe. Stipules ſcarcely any. Flowers axillary or terminating; ſolitary, or more often many[a]. They are natives of the Cape of Good Hope.

1. This is a ſhrub with very handſome flowers. Stem four feet high, ſtout, ſmooth and even. Leaves alternate, remote, broad-lanceolate, quite entire, acute, rigid, dagger-pointed, pungent. Head terminating, ſeſſile, ſmooth, the ſize of an Artichoke, ſurrounded by the leaves like a calyx, of the ſame length with the corollets. The loweſt ſegment of the calyx the length of the whole corolla, and of the ſame breadth alſo, coloured or petaloid, emarginate-trifid at the top. Corolla tawny. The manner in which the wings wrap round each other before the flower opens, is very ſingular[b].

2. Stem ſhrubby, determinately branched, ſmooth and even, angular. Leaves flat, acuminate, ſtiff, ſmooth and even, one-nerved, alternate, much longer than the internodes, decurrent a little on the back and edges. Stipules minute, in pairs, awl-ſhaped. Head made up of a raceme, terminating, ſeſſile, not longer than the leaves. Calyx hoary, hairy, with the lower ſegment longer. Corolla yellow. Dorſal ſtamen diſtinct. Germ hirſute. Stigma ſimple.

3. See the deſcription under Borbonia lævigata.

4. This reſembles Indigofera ſericea. The flowers are in bundles: the corollas ſmooth and even: the ſtamens truly diadelphous[c].

Branches round, tomentoſe, warted, determinately divided: branchlets in whorls, divided into others alſo in whorls, thickly tomentoſe, ſilvery. Leaves ſcattered, tomentoſe on both ſides, ſilvery, ſhining, frequent, ſcarcely an inch long, longer than the internodes, ſpreading a little. Heads or ſpikes ſeſſile at the ends of the branchlets, fortified with leaves. Corolla red. Germ hirſute[d].

Introduced from the Cape in 1774, by Mr. Francis Maſſon[e].

* *

5. This is allied to the preceding[f].

DESCRIPTIONS, &c.

1. Height fixteen or eighteen feet, with a rough bark; branches and leaves in pairs. Leaves oblong, pointed, a little ſerrate. Pedunclés axillary, ſuſtaining many pyramidal ſcaly heads, about the ſize of a large gray pea, in which are many ſmall yellow flowers between the ſcales.

[It is a ſhrub with round pale ſtems, compreſſed at the joints. Leaves lanceolate-ovate, ſerrate beyond the middle, petioled, rugged. Pedunclés axillary, oppoſite, very ſhort. Heads imbricate backwards, with innumerable ſcales, four-cornered, ovate, having one flower within each ſcale *.

Corolla funnel-form. Fruits on long pedunclés. Heads ovate-globular; ſcales very broad, emarginate at the baſe, mucronate at the tip, concealing the calyxes, the valves of which are hiſpid. Seeds two, coadunate, ovate, ſomewhat bony, convex and ſmoothiſh on one ſide, flat or ſlightly concave on the other, whitiſh *.

Gærtner is for expunging this genus, and uniting it with Blairia. He remarks that the calyx is certainly not ſuperior.

Found at La Vera Cruz by Dr. Houſtoun, and cultivated by Mr. Miller before 1733.

2. This is a ſhrub ten feet in height, the whole odoriferous and aromatic; dividing into woody, round, weak branches, that bend down unleſs they are ſupported; the younger ones are quadrangular and flower-bearing. Leaves oval-lanceolate, acuminate at both ends, entire, or ſometimes irregular at top, with a few inciſures, ſmooth underneath, ſmoothiſh above, petioled, oppoſite, two or three inches long. Pedunclés axillary, ſolitary, oppoſite, almoſt the length of the petioles, ending in an imbricate hemiſpherical head, the ſcales of which are rhomboid-cordate, acuminate, entire, one under each flower. Flowers ſmall, each on a very ſhort peduncle. Corolla white. Capſules connate, eaſily ſeparable when ripe, and reſembling a two-celled, two-valved capſule: or each capſule may be taken for the cover of the ſeed, and then there will be no pericarp. This plant connects the Stellate with the Verticillate plants, and yet is of neither order. Native of Carthagena in New Spain *.

Mr. Miller gives this ſpecies in the laſt folio edition of the Dictionary, but he does not ſay that he had cultivated it.

3. Linnæus deſcribes this in the mantiſſa under the name of *Lippia ovata*. Gærtner ſeparates it from Lippia, on account of the inverted ſituation of the embryo, and names it *Dalea Lippiatrum*. L'Heritier has placed it among the *Selagos*, where a deſcription of it will be found.

4. Stem four-cornered, hoary with ſhagginеſs. Leaves oppoſite, petioled, long, hairy above, hoary beneath. Pedunclés axillary, ſeveral, elongated into a panicle, branching. Pedicels terminating in ovate heads, ſupported by two bractes. Flowers minute, white. Found in America by Mutis *.

5. This ſhrub has often ſeveral ſtems from the ſame root, each no bigger than a gooſe quill, round, woody, brownish black, from three to ſix feet in height, ſlender, and requiring ſupport: twigs many, oppoſite, having ſharp prickles one third of an inch long, and oppoſite leaves, half an inch in diameter, a little pointed at the ends, almoſt round, yellowiſh green, ſmooth, ſomething like thoſe of Nummularia, and very ſtrong ſcented like Pulegium. Petioles the eighth of an inch in length. The flowers come out at the top, are ſmall, many together, of the colour, and ſomewhat reſembling thoſe of Spiræa Theophraſti, though not ſo cloſe ſet, nor ſo handſome. Seeds ſmall, oblong, channelled, brown. Native of Jamaica *.]

PROPAGATION AND CULTURE.

Theſe ſhrubs, being natives of the Continent and iſlands of the Weſt Indies, muſt be preſerved in a bark ſtove. The ſeeds ſhould be ſown on a hot-bed, and the plants treated as other ſhrubby plants from the ſame country: by keeping them always in the ſtove, plunged in the bark bed, obſerving to give them a large ſhare of air in warm weather, and to refreſh them frequently with water. In winter they muſt be watered more ſparingly, and be kept in a moderate degree of warmth, otherwiſe they will not live through the winter, eſpecially when young; but when they have acquired ſtrength, they may be preſerved with a leſs ſhare of warmth.

As the plants advance in their growth, ſhift them into larger pots, but this ſhould not be too often repeated. Once every ſpring will be ſufficient, for theſe and many other exotic plants do not thrive ſo well when frequently removed, as when they are permitted to fill the pots with their roots. Shift them in April, at which time the tan of the hot-bed ſhould be ſtirred, and freſh tan mixed with it, to increaſe the heat. The earth in which theſe plants are placed, ſhould be freſh and light, but not too rich.

DESCRIPTION, *&c.*

1. The trunk of the Sweet-Gum tree is commonly two feet in diameter, ſtraight, and free from branches to the height of about fifteen feet; from which the branches ſpread and riſe in a conic form to the height of forty feet and upwards from the ground. Leaves five-pointed, divided into ſo many deep ſections, (or ſometimes ſeven) and ſet on long ſlender petioles. In february before the leaves are formed, the bloſſoms begin to break forth from the tops of the branches into ſpikes of yellowiſh-red, pappoſe, globular flowers, which ſwell gradually, retaining their round form, to the full maturity of their ſeed-veſſels, which are thick ſet with pointed hollow prouberances, and ſplitting open diſcharge their ſeeds. Each cell contains a ſeed, winged at one end with many ſmall grains, diſtinct from the ſeed[a]. Theſe, which Linnæus calls chaffy corpuſcles, according to Gærtner, are immature germs. There are two capſules in each cell of the ament; they are grooved, ſhining, and of a bay-ferruginous colour. Common receptacle globular, honey-combed, with the female bell-ſhaped calyxes united; proper none, beſides the inner walls of the capſules, to which the germs are fixed all round. Seeds as many as ſixteen in a capſule, oblong elliptic, compreſſed like a lens[b].]

The leaves are ſhaped ſomewhat like thoſe of the leſſer Maple, but are of a dark green colour, with their upper ſurfaces ſhining. A ſweet glutinous ſubſtance exſudes through their pores in warm weather, which renders them clammy to the touch.

[The leaves of this ſpecies are diſtinguiſhed from thoſe of the ſecond by the little tufts of hairs placed where the veins divide from the midrib.

The wood of this tree is good timber, and is uſed in wainſcotting, &c. The grain is fine, and ſome of it beautifully variegated; but when wrought too green is apt to ſhrink, to prevent which no leſs than eight or ten years is ſufficient to ſeaſon the planks. From between the wood and the bark iſſues a fragrant gum, which trickles from the wounded trees, and by the heat of the ſun congeals into tranſparent drops, which the Indians chew, as a preſervative to their teeth. It ſmells ſo like Balſam of Tolu, that it is not eaſy to diſtinguiſh them. The Bark is alſo of ſingular uſe to the Indians for covering their huts[c].

Native of North America, in low clavey ground.—Cultivated in the garden of Compton, Biſhop of London (in 1688) by his gardener George London. It was ſent over from Virginia by Baniſter[d].]

2. The leaves of this have their lobes ſhorter, and much more ſituated on their borders, they end in blunt points, and are not ſerrated. [They have alſo none of thoſe tufts of hair which are found on the leaves of the firſt ſort. Its native country is unknown. According to Mr. Miller,] the ſeeds were ſent to Mr. Peyſſonel from the Levant, to the King of France's garden at Marli. Monſ. Richard, the King's gardener, ſent ſome of them to Mr. Miller, [who cultivated this tree in 1759[e].]

PROPAGATION AND CULTURE.

The Sweet-Gum tree is hardy enough to endure the ſevereſt cold of this country in the open air. It is commonly propagated by layers; but when raiſed from ſeeds, it grows to be a much fairer tree.

[a] Catesby. [b] Gærtner. [c] Catesby.
[d] Ray hiſt. 1681. [e] Hort. kew.

The ſeeds of this tree, if ſown in the ſpring, commonly remain in the ground a whole year before the plants come up; ſo that the ſureſt way to raiſe them is, to ſow the ſeeds in boxes or pots of light earth; which may be placed in a ſhady ſituation during the firſt ſummer, and in autumn they may be removed where they may have more ſun; but if the winter ſhould prove ſevere, it will be proper to cover them with Peas-haulm, or other light covering, which ſhould be taken off conſtantly in mild weather. In the following ſpring, if theſe boxes or pots are placed upon a moderate hot-bed, it will cauſe the ſeeds to come up early, ſo that the plants will have time to get ſtrength before the winter; but during the firſt and ſecond winters, it will be proper to ſcreen the plants from ſevere froſt, but afterwards they will bear the cold very well.

DESCRIPTION, *&c.*

1. This is a native of North America, where it grows ſo large as to be a tree of the firſt magnitude, and is generally known through all the Engliſh ſettlements by the title of Poplar. Of late years there has been great numbers of theſe trees raiſed from ſeeds in the Engliſh gardens, ſo that now they are become common in the nurſeries about London, and there are many of the trees in ſeveral parts of England which do annually produce flowers. The firſt tree of this kind which flowered here, was in the gardens of the late Earl of

Peterborough, at Parſons Green near Fulham, which was planted in a wilderneſs among other trees; before this was planted in the open air, the few plants which were then in the Engliſh gardens, were planted in pots and houſed in winter, ſuppoſing they were too tender to live in the open air; but this tree ſoon after it was placed in the full ground, convinced the gardeners of their miſtake, by the great progreſs it made, while thoſe which were kept in pots and tubs increaſed ſlowly in their growth; ſo that afterward there were many others planted in the full ground, which are now arrived to a large ſize, eſpecially thoſe which were planted in a moiſt ſoil. One of the handſomeſt trees of this kind near London, is in the garden of Mr. Jones at Waltham Abbey; and at Wilton, the ſeat of the Earl of Pembroke, there are ſome trees of great bulk; but the old tree at Parſons Green is quite deſtroyed, by the other trees which were ſuffered to over-hang it, and rob it of its nouriſhment, from a fear of taking down the neighbouring trees, left by admitting the cold air to the Tulip tree it would injure it.

[Mr. Darby at Hoxton and Mr. Fairchild, ſeem to have been the firſt who raiſed this tree in any quantity from ſeeds, and from them the gardens abroad were chiefly ſupplied [a]. Biſhop Compton, however, cultivated it at Fulham in 1688 [b]. There is a fine tree in Mr. Ord's garden at Walham Green, every year covered with bloſſoms [c].]

The young ſhoots of this tree are covered with a ſmooth purpliſh bark; they are garniſhed with large leaves, whoſe foot-ſtalks are four inches long; they are ranged alternate; the leaves are of a ſingular form, being divided into three lobes; the middle lobe is blunt and hollowed at the point, appearing as if it had been cut with ſciſſars. The two ſide lobes are rounded, and end in blunt points. The leaves are from four to five inches broad near their baſe, and about four inches long from the foot-ſtalk to the point, having a ſtrong midrib, which is formed by the prolongation of the foot-ſtalk. From the midrib run many tranſverſe veins to the borders, which ramify into ſeveral ſmaller. The upper ſurface of the leaves is ſmooth, and of a lucid green, the under is of a pale green. The flowers are produced at the end of the branches; they are compoſed of ſix petals, three without, and three within, which form a ſort of bell-ſhaped flower, whence the inhabitants of North America gave it the title of Tulip. Theſe petals are marked with green, yellow, and red ſpots, making a fine appearance when the trees are well charged with flowers. The time of this tree's flowering is in July, and when the flowers drop, the germ ſwells, and forms a kind of cone, but theſe do not ripen in England. [Gærtner ſays that he has diſſected more than five hundred ſcales, or *amaræ*, as he calls them, without finding a ſingle fertile ſeed. The upper ſcales have only one ſeed in them, but the lower ones have conſtantly two.]

Mr. Cateſby, in his Natural Hiſtory of Caroſina, &c. ſays, there are ſome of theſe trees in America, which are thirty feet in circumference; that the boughs are unequal and irregular, making ſeveral bends or elbows, which render the trees diſtinguiſhable at a great diſtance, even when they have no leaves upon them. They are found in moſt parts of the northern continent of America, from the Cape of Florida to New England, where the timber is of great uſe, particularly for making of periaugues, the trunks of theſe being large enough to be hollowed into the ſhape of thoſe boats, ſo they are of one piece.

[Mr. Marſhall deſcribes the Tulip tree as ſeventy or eighty feet in height. He mentions two varieties, one with yellow, and the other with white wood; the firſt ſoft and brittle, much uſed for boards and heels of ſhoes, alſo turned into bowls, trenchers, &c.; the white heavy, tough and hard, ſawed into joiſts, boards, &c. for building. He remarks that the flower has ſometimes ſeven petals or more.

Kalm obſerves, that it is very agreeable at the end of may to ſee one of theſe large trees, with its ſingular leaves, and covered for a fortnight together with flowers, which have the ſhape, ſize, and partly the colour of Tulips. The wood is uſed for canoes, whence the Swedes in North America call it Canoe-tree, for boards, bowls, diſhes, ſpoons, and all ſorts of joiners work. Kalm ſpeaks of having ſeen a barn of conſiderable ſize, the ſides and roof of which were made of a ſingle Tulip-tree ſplit into boards. But there is one inconvenience attending it, for there is no wood that contracts and expands itſelf ſo much as this. The bark is diviſible into very thin laminæ, which are tough like baſt. It is pounded, and given to horſes who have the bots. The roots are ſuppoſed to be as efficacious in agues as Jeſuit's bark.

2. This is a middle-ſized tree, with ſpreading branches. Leaves ovate, acuminate, quite entire, ſmooth, alternate. Flowers pale, large, without ſcent, heaped at the ends of the branches, one on a peduncle. Calyx none. Petals nine, ovate, thick, forming a tube at bottom, reflex at top. Filaments about ſixty, thick, very ſhort, placed on the baſe of the receptacle elongated. Anthers long, acuminate, bent in, perforated at top. Germs about fifty, flattiſh, acute, imbricate, but without ſcales. Stigmas ſeſſile. Native of China, near Canton, and of Amboina [d].

Loureiro has two other ſpecies which he names *L. Figo* and *L. Cera*, but not knowing whether they belong to this genus or to that of Magnolia, I have not ventured to inſert them among the ſpecies.]

PROPAGATION AND CULTURE.

This tree is propagated by ſeeds, which are now annually imported in great plenty from America. Theſe may be either ſown in pots or tubs filled with light earth from the kitchen-garden, or in a bed in the full ground. Thoſe which are ſown in the firſt way, may be placed on a gentle hot-bed, which will forward their growth, ſo that the plants will acquire more ſtrength before winter. If they are thus treated, the glaſſes of the hot-bed ſhould be ſhaded from the ſun every day, and the earth in the pots ſhould be frequently refreſhed with water, for unleſs it is kept moiſt, the ſeeds will not grow; but this muſt be done with care, ſo as not to make it too wet, which will rot the ſeeds. When the plants appear, they muſt be ſtill ſhaded in the heat of the day from the ſun, but freſh air muſt be admitted daily to prevent their drawing up weak, and as the ſeaſon advances, they muſt be gradually hardened to bear the open air. While the plants are young, they do not care for much ſun, ſo they ſhould be either ſhaded or placed where the morning ſun only ſhines upon them; they muſt alſo be conſtantly ſupplied with water, but not have it in too great plenty. As the young plants commonly continue growing late in the ſummer, ſo when there happens early froſts in autumn, it often kills their tender tops, which occaſions their dying down a conſiderable length in winter, therefore they ſhould be carefully guarded againſt theſe firſt froſts, which are always more hurtful to them than harder froſts afterward, when their ſhoots are better hardened; however, the firſt winter after the plants come up, it will be the better way to ſhelter them in a common hot-bed frame, or to arch them over with hoops, and cover them with mats, expoſing them always to the open air in mild weather.

The following ſpring, juſt before the plants begin to ſhoot, they ſhould be tranſplanted into nurſery-beds, in a ſheltered ſituation, where they are not too much expoſed to the ſun. The ſoil of theſe beds ſhould be a ſoft gentle loam, not too ſtiff, nor over light; this ſhould be well wrought, and the clods well broken, and made fine. There muſt be great care taken not to break the roots of the plants in taking them up, for they are very tender; they ſhould be planted again as ſoon as poſſible, for if their roots are long out of the ground, they will be much injured thereby. Theſe may be planted in rows at about a foot diſtance, and at ſix inches diſtance in the rows, for as they ſhould not remain long in theſe nurſery-beds, ſo this will be room enough for them to grow; and by having them ſo cloſe, they may be ſhaded in the ſummer, or ſhel-

[d] Loureiro.

tered

tered in the winter, with more eaſe than when they are farther apart.

When the plants are thus planted, if the ſurface of the beds is covered with rotten tanners bark, or with moſs, it will prevent the earth from drying too faſt, ſo that the plants will not require to be ſo often watered, as they muſt be where the ground is expoſed to the ſun and air; after this, the farther care will be to keep them clean from weeds, and if the latter part of ſummer ſhould prove moiſt, it will occaſion the plants growing late in autumn, ſo the tops will be tender, and liable to be killed by the firſt froſts. In this caſe, they ſhould be covered with mats to protect them.

If the plants make great progreſs the firſt ſummer, they may be tranſplanted again the following ſpring; part of them may be planted in the places where they are to remain, and the other ſhould be planted in a nurſery where they may grow two or three years to acquire ſtrength before they are planted out for good; though the younger they are planted in the places where they are to ſtand, the larger they will grow, for the roots run out into length, and when they are cut it greatly retards their growth, ſo that theſe trees ſhould never be removed large, for they rarely ſucceed when they are grown to a large ſize before they are tranſplanted. Some trees I have ſeen removed pretty large, which have ſurvived their removal, but young plants of two or three years old which were planted near them, were much larger in fifteen years than the old ones.

When the ſeeds are ſown upon a bed in the full ground, the bed ſhould be arched over with hoops, and ſhaded in the heat of the day from the ſun, and frequently refreſhed with water; as alſo ſhould the plants when they appear, for when they are expoſed much to the ſun they make but ſmall progreſs. The care of theſe in ſummer muſt be to keep them clean from weeds, ſupplying them duly with water, and ſhading them from the ſun in hot weather; but as theſe ſeeds will not come up ſo ſoon as thoſe which were placed on a hot-bed, they generally continue growing later in autumn, therefore will require ſhelter from the early froſts in autumn; for as the ſhoots of theſe will be much ſofter than thoſe of the plants which had longer time to grow, ſo if the autumnal froſts ſhould prove ſevere, they will be in danger of being killed down to the ſurface of the ground, by which the whole ſummer's growth will be loſt, and ſometimes the plants are entirely killed by the froſt the firſt winter, if they are not protected.

As theſe plants will not have advanced ſo much in their growth as the other, they ſhould remain in the ſeed-bed to have another year's growth before they are removed, therefore all that will be neceſſary to obſerve the ſecond year is to keep them clean from weeds; and now they will not be in ſo much danger of ſuffering from the warmth of the ſun as before, therefore will not require ſuch conſtant care to ſhade them; nor ſhould the watering of them be continued longer than the ſpring, for if the autumn ſhould prove dry, it will prevent the plants from ſhooting late, and harden thoſe ſhoots which were made early in the year, whereby the plants will be in leſs danger from the early froſts.

After the plants have grown two years in the ſeed-bed, they will be ſtrong enough to remove, therefore, in the ſpring, juſt at the time when their buds begin to ſwell, they ſhould be carefully taken up, and tranſplanted into nurſery-beds, and treated in the ſame way as has been before directed for the plants which were raiſed on a hot-bed.

There are ſome people who propagate this tree by layers, but the layers are commonly two or three years before they take root, and the plants ſo raiſed, ſeldom make ſuch ſtraight trees as thoſe raiſed from ſeeds; though indeed they will produce flowers ſooner, as is always the caſe with ſtinted plants.

This tree ſhould be planted on a light loamy ſoil, not too dry, on which it will thrive much better than upon a ſtrong clay, or a dry gravelly ground; for in America they are chiefly found upon a moiſt light ſoil, where they will grow to a prodigious ſize, though it will not be proper to plant theſe trees in a ſoil which is too moiſt in England, becauſe it might endanger the rotting of the fibres of the roots, by the moiſture continuing too long about them, eſpecially if the bottom be clay, or a ſtrong loam, which will detain the wet.

[To raiſe them in the open ground the beginning of march, prepare a bed of good mellow rich earth well mixed with old rotten cow-dung, expoſed to the ſun, and ſheltered from cold winds: place an old frame over the bed, and having ſown the ſeeds, ſift over them, half an inch thick, a ſoil compoſed ſome months before of one load old paſture earth, one of well-rotted cow-dung, and half a load of ſea or fine pit-ſand. Some of theſe ſeeds will probably make their appearance in nine or ten weeks, but much the greater part will lie in the ground till next ſpring. Water the beds therefore no more than barely ſufficient to cheriſh the plants that have appeared: for four or five weeks ſcreen them from the ſun during the heat of the day, but afterwards let them receive its full influence. In bad weather, during winter, throw double mats over the frames.

In march the ſucceeding year, pick off all moſſy, hard cruſted earth from the bed, ſmooth it, and ſift on ſome fine, rich mould. The end of april, or beginning of may, plants will appear in abundance, when they muſt be frequently but gently watered. Till the beginning of auguſt they muſt be ſcreened from the mid-day ſun, by part of an old reed fence, or by nailing ſome thin boards together high enough to ſhade the bed. After this, no farther care is neceſſary, but frequent moderate waterings, and to throw a mat over the frame during any ſevere winter ſtorm.

The beginning of april, next ſeaſon, take up the plants carefully with a trowel, without bruiſing the roots, and if they cannot be planted immediately, mix a pail-full of ſifted mould and water, to the conſiſtence of pap; draw the plants through it, till as much adhere as covers their roots and fibres; in this condition they may be kept ſeveral days out of the ground. Cut only a little of the tap-root ſmoothly off, but let all the fibres remain; and then plant them in drills cut out with the ſpade, at a foot diſtance row from row, and ſix inches in the row. Plant five of theſe lines, and then leave an alley three feet wide. Water them frequently and plentifully during the ſummer months; throw mats over them in caſe of very ſevere froſt, the firſt winter, and let them remain two years. Then remove them to another nurſery, in rows three feet and a half diſtant, and eighteen inches in the row, and let them continue three years. Being now ſix or ſeven feet high, they will be of a good ſize for planting where they are to remain. No tree bears pruning its roots or branches worſe than this.

It is a tree of extraordinary beauty and ſtateline's, and highly deſerves a place in all noble and elegant plantations *.

DESCRIPTIONS, *&c.*

1. This elegant little plant rifes generally to the height of fourteen or fixteen inches or more: it is not much divided, but all the branches fhoot commonly to the fame height, and are furnifhed with oblong pointed leaves, placed oppofite. The flowers are large in proportion to the plant, are generally longer than the leaves, and ftand at the extremities of the branches [a].

According to Sloane, it rifes to about four or five feet high, being branched on every fide. The branches and twigs are woody. The pairs of leaves at an inch diftance from each other, an inch and half long, and half as much broad in the middle, fmooth, dark green, on petioles an eighth part of an inch in length. Flowers yellow, fuperior. Capfule pyramidal, oblong, covered with a few fmall leaves, three-celled, with great plenty of fmall brown feed in each cell.

Native of Jamaica, in a dry, fandy, but cool foil.

2. Browne remarks, that this plant may be deemed a variation of the foregoing: or that they are at leaft fo very like in the general make and habit, that the form of the leaves is almoft the only difference. Swartz, however, obferves, that the leaves are always heart-fhaped, the upper ones only being ovate and feffile; the corollas are alfo rather larger.

Native of Jamaica.

3. 4. 5. Natives of Jamaica.

6. Native of the mountains of Guadeloupe [a].

7. See the defcription under *Bignonia fempervirens*. Linnæus obferves that the feed-veffels are cordate, fimple filiques.

8. The whole plant fmooth. Stem upright, branched, round, leafy. Branchlets from the axils of the upper leaves, flowering at top. Leaves oppofite, oval rather than ovate, acute, quite entire, veined, paler underneath. Petioles fhort, connate-embracing, keeled. Stipules none. Flowers on few-flowered fimple umbels, terminating the ftem and branchlets. Pedicels upright, one-flowered. Bractes like the leaves, but fmaller, two or three at the bafe of each umbel. Calyx bell-fhaped, five-cleft; fegments unequal, acute: Corolla five times as long as the calyx, bell-funnel-form, with equal, acute clefts, and of a yellow colour. Filaments inferted towards the bafe of the corolla, equal, the length of the corolla. Anthers twin, cordate-oblong, opening in front. Germ fuperior, ovate. Style cylindric, after flowering twifted. Stigma two-lobed; lobes obovate, flat. Capfule ovate, acute, two-celled, two-valved; the valves bent in forming the partition. Found in South America by Mutis [a].

9. Stem herbaceous, fimple, round, fmooth, from two to three feet in height. Leaves elliptic-oblong, quite entire, bluntifh. Panicle divided into two or three long racemes. Flowers alternate, remote, directed one way, pendulous, yellow. Calyx globular. Tube of the corolla fomewhat recurved, gradually widening. Genitals afcending towards the tip. Germ pyramidal, attenuated into the compreffed ftyle. The two lobes or plates of the ftigma recurved and tuberculed. Capfule fmooth, hanging down with the ftyle.—The herb is very bitter, and ftrongly purgative. Native of Surinam [a]. Aublet's plant, which is cited as fynonymous in the Supplement, is diftinct from this, and a new fpecies [b].

PROPAGATION AND CULTURE.

7. See Bignonia fempervirens. The reft being natives of South America and the iflands of the Weft-Indies, are much more tender, and muft be nurfed in the bark-ftove.

Lin. ſpec. 191. *ſyſt.* 185. *Reich.* 1. 387. *Der.* 1. 13. *t.* 7.
Seeds only two, calyxes ſpreading.

DESCRIPTIONS, &c.

1. Root perennial, ſtrong. Stems erect, roundiſh, rough with cloſe-preſſed briſtles, and clothed with alternate, entire leaves, which are ſlightly revolute on their margin, hairy beneath, rough above with minute cartilaginous tubercles. Each of the numerous flowering-branches terminates in a recurved leafy ſpike of pale yellowiſh flowers: in the ſeeding ſtate theſe branches become erect, much elongated, and the leaves they bear are conſiderably enlarged, being broader than thoſe on the ſtem. It is ſeldom that more than two ſeeds are perfected in each flower: they are exquiſitely poliſhed, of a gray or yellowiſh hue, very hard, but brittle, ſeeming of a ſtony ſubſtance; whence the generic name, and whence alſo the ancient celebrity of theſe ſeeds as a cure for the ſtone, without the leaſt ſhadow of a reaſon[a].

Gærtner calls them ſtony, egg-ſhaped nuts, marked on the inſide with a ſtreak and two obſolete lines, imperforate, one-celled, valveleſs: ſeed ovate-beaked, black-brown.

Native of moſt parts of Europe, in dry, gravelly and chalky ſoils, with us in general ſparingly, but common in ſome woods. It flowers in may and june.

2. Root annual, ſmall, and not much branched; its bark abounding with a deep red dye, which ſtains paper, linen, &c. and is eaſily communicated to oily ſubſtances. Hence the name of Baſtard Alkanet, ſometimes given to this plant. Linneus, in his Flora Suecica informs us, that the country girls in the north of Sweden uſe the root to ſtain their faces on days of feſtivity.—Stem upright, a foot high or more, round or ſlightly angular, rough with cloſe-preſſed hairs, often much branched at top. Leaves alternate, lanceolate, entire, rigid, ſeſſile, rough with briſtly hairs cloſe-preſſed, ſtanding out from the edge. Flowers ſolitary, nearly ſeſſile, in the axils of the upper leaves. Corolla ſmall and white, with five ſwellings round its orifice, exactly as in L. purpuro-cæruleum. Very near the bottom of the tube ſtand the five very ſhort minute ſtamens, on a level with the ſtyle, which is about half as long as the tube. Seeds brown, rugged; rather covered with hard tubercles than wrinkled: two, three, or four, but generally three, with one abortive: ſometimes when there are four perfect ſeeds, there are two others abortive, and ſix diviſions in the calyx. The calycine ſegments are narrower than in L. officinale, and after flowering are three or four times as long as the ſeeds, whereas in the preceding ſpecies they are not twice the length[b]. Gærtner ſays, the nuts are ſtony, ovate, acuminate-beaked, convex on one ſide, angular on the other by means of a keel along the middle, rugged all over with tubercles.

Frequent in corn fields and waſte places, flowering from may to july.

[a] Engl. bot. [b] Engl. bot. Withe. Pollich.

3. This is a ſhrubby ſpecies, found in Teautea and Savage iſlands[c].]

4. Root perennial. Stems ſeveral, very hairy, about a foot and half high. Leaves ſeſſile, alternate. Flowers in ſhort reflexed ſpikes at the ends of the branches. Corolla white, longer than the calyx, the ſegments ending in acute points.

[Linneus remarks, that the dots ſcattered over the leaves are excavated, and that the wider of theſe have a briſtle iſſuing from them.

Native of Virginia and Maryland.] It flowers here in june, and the ſeeds ripen in autumn.

[Cultivated by Mr. Miller, in 1759.

5. Root fuſiform, two inches long, annual. Stems ſeveral, a finger's length, quite ſimple, ſhaggy with hairs, as is the whole plant; the lateral ones decumbent, the middle one erect. Leaves ſeſſile; thoſe next the root near two inches long, narrowed towards the baſe; thoſe on the ſtem an inch long and blunt. Spike the length of the ſtem, cloſely imbricate. Bracte linear-lanceolate at the baſe of the calyx, the length of the flower. Calyx deeply five-parted, with linear, bluntiſh ſegments: when fruit-bearing twice the ſize. Corolla longer than the calyx, with a filiform tube. Nuts four, obcordate-triangular, even, ſhining, convex on the outſide, flat on the inſide.

It differs from L. apulum (Myoſotis apula. *Lin.*) to which it is very nearly allied, in having a laxer ſtem, longer blunt leaves, a ſolitary ſpike terminating the ſtem, and as long if not longer than it, narrower blue corollas, and ſeeds twice as big[d].

Native of Egypt.

6. Stem barren upright, with fewer hairs. Leaves lanceolate, narrower at the baſe, quite entire, blunt, with dewy hairs on each ſide. Flowering-branches from the axils of the lower leaves, with cordate ſmaller bractes, having alſo dewy hairs. Flowers ſubpedunculed, yellow. Filaments ſhorter than the tube with black anthers[e].] It is a perennial plant, with long trailing branches; the under leaves are long, broad and hairy, diminiſhing as they approach the top. The flowers are about the ſame ſize with thoſe of common Bugloſs: there is a ſucceſſion of them great part of the year.

Native of the Levant. [Cultivated in 1713, in the botanic garden at Cheliſea. It flowers in may and june[f].

7. The long woody perennial root produces many round hairy leafy ſtems, moſt of which are procumbent, and throw out roots; the flowering ones only are perfectly erect, and from twelve to eighteen inches high. Leaves numerous, alternate, acute, clothed with ſhort cloſe-preſſed briſtles, which on the upper ſide of the leaf often ariſe from minute white tubercles, or warts, as in many of this natural order. The beautiful flowers appear in april or may, ſtanding erect in a ſort of double leafy ſpike, with the extremities a little curved downwards before flowering. Calyx hairy, divided to the baſe into five very narrow linear obtuſe ſegments. Corolla firſt purple, then blue, with a pale reddiſh tube; round its orifice are five blunt hairy ſwellings, which however do not cloſe it. Filaments ſomewhat ſhorter than the tube, and united with it half way up. Style about the ſame length, with a ſlightly-notched ſtigma. Germ and ſeeds very ſmooth; the latter frequently abortive, as in other plants that increaſe much by their roots[g].—The ſegments of the calyx, after flowering, become much longer, as in L. arvenſe[h], and other plants of this natural order.

Native of moſt of the temperate parts of Europe. Found in the Weſt of England, as in Somerſetſhire near Taunton. Near Denbigh in Wales. Mr. Latham diſcovered it in a chalky ſoil near Greenhithe in Kent.

8. This is an annual plant, a hand or a ſpan in height, like the ſecond ſpecies in minature. Stem upright, filiform, with one or two branches, ſubpubeſcent. Leaves alternate, ſeſſile, very ſhortly ſtrigoſe or hairy, bluntiſh. Calyxes on the branches all

[c] Forſter. [d] Vahl. [e] Linn. [f] Hort. kew.
[g] Engl. bot. [h] Withering.

directed one way, subpedicelled, alternate, oblong, five-parted, as in L. arvense. Corollas very small, blue: tube the length of the calyx; limb minute.

Native of Egypt[1].]

9. Root perennial, running deep into the ground. Stem upright, shrubby, from two to three feet high, pretty closely set with hairs. The flowers are produced in short reflex spikes. Calyxes hairy. Corollas reddish purple, changing to a deep purple; the two upper segments are turned back.

[Native of the South of Europe and the Levant. Cultivated in 1683, by Mr. James Sutherland. It flowers in may and june[2].

10. Stem a long span in height, with a white bark, villose at bottom, hispid at top: branches the height of the stem, once or twice divided at top. Leaves sessile, remote, blunt, with white callosities all over them, and with rigid concolor bristles towards the end. Spike terminating, revolute, extremely hirsute; with a linear leaflet, longer than the calyx, and ciliate, at the base of each flower. Tube of the corolla villose. It varies with the branches more or less erect.

11. This is a small stiff shrub, upright, a long span in height, hoary, muricated at top, hispid, very much branched: branches dichotomous. Leaves half embracing, patulous at the tip, warted with white callosities at the edge, small. Spike lateral, half an inch in length[1].

12. Root annual. Stem herbaceous, a hand in height, round, hispid, upright, dividing at top into two almost upright branches, seldom more. Stem-leaves alternate, sessile, tongue-shaped, spreading very much or recurved, channelled, blunt, hispid, somewhat rugged, an inch long, veinless. Branch-leaves lanceolate, acute, erect, smaller. Flowers alternate, directed one way, opposite to the branch-leaves, on short round hispid peduncles. Calyx hispid, a little shorter than the corolla. Corolla blueish white, small; border flattish. Filaments scarcely visible with the naked eye. Germs only two. Seeds ovate, acuminate, even, converging.

Native of Spain, between Madrid and Cadiz[m].

PROPAGATION AND CULTURE.

These plants may be cultivated by sowing their seeds soon after they are ripe, in a bed of fresh earth, allowing them room, and keeping them clear from weeds. They will thrive in almost any soil and situation: [and if the seeds be permitted to scatter, the plants will in general rise without care. Some of the sorts (6. 7.) are not without their beauty. The first being wild is seldom cultivated, and the second is a common weed among corn.

DESCRIPTION, *&c.*

The root shoots out long running fibres, which take root afresh, and thus in a short time cover the brink of the lakes with tufts of semicylindrical linear acute leaves, about two inches long. Three, four or more naked stalks arise from between the leaves, about an inch and half long, terminated each with one greenish male flower. The female flowers are sessile, commonly two, sometimes three, at the base of the male stalk[1].

Linnæus in his earlier works, following Tournefort, placed this plant with the Plantagos. It has indeed their flower; but the stamens and pistils being found in separate flowers, though on the same plant, and the fruit being different from that of the Plantains, he afterwards separated it from that genus. He remarks, that the male flower is on a stalk, taller than the female: the female flower sessile at the root, and the style often as long as the stalk of the male flower.

Native of the north of Europe, on the shores of lakes.

Ray, who ranges it with the Rush-Grasses, and calls it the smallest Marsh Plantain, observed it near Cambridge, Glasgow and Penzance. Frequent in Scotland and some parts of Wales. On Hounslow heath. Near Lowestoft, Suffolk. Hoseley lough, Northumberland, &c. On the margins of all the lakes in Ireland, that have gravelly shores.

DESCRIPTION, *&c.*

This is an elegant annual plant, riſing from a fibrous white root, the thickneſs of the little finger. It is ſubdivided into ſpreading branches; and is armed all over with ſtiff ſhining brownish prickles, that ſting like the nettle. Stems round, whitiſh green, marked here and there with ſhort brown longitudinal lines. Leaves pinnatifid, petioled, irregularly alternate, rough, blunt: the ſegments pinnatifid, tooth ſinuate; in the upper ones leſs divided, but very unequal. The uppermoſt leaves are only ſinuate. All the branches terminate in very looſe racemes. Peduncles ſolitary, an inch long, both axillary and oppoſite to the leaves. Bractes none. Flowers elegant but void of ſcent. Calycine ſegments acuminate, hairy. Petals ſomewhat hairy, and finally turned back. The filaments are erect, but after the exploſion of the pollen are ſucceſſively bent back. Germ hairy, half inferior. Capſule rough-haired, furrounded at top with the ſhrivelled ſegments of the calyx. The petals are yellow; the nectaries white variegated with red and green dots. Theſe are at a little diſtance from each other, the filaments whilſt they remain upright occupying the interſtices, and the anthers exploding their pollen whilſt they are cloſe to the ſtigma. After the fecundation is completed the filaments retire gradually under the arches of the petals. Adanſon calls theſe ſmall laminæ petals, and therefore makes the number of the petals ten.

Feuillée ſays, that the corolla in his plant is red and deep green beneath, and that the leaves are oppoſite, Adanſon affirms that the capſule is five-valved, and the petals connected, which is not the caſe in Jacquin's plant. Perhaps Feuillée's and Adanſon's plant may be the ſame, and different from Profeſſor Jacquin's.

Native of South America, and cultivated at Vienna before 1767*.

Depreſſed, leaves lanceolate, ſtem fleſhy.

DESCRIPTIONS, *&c.*

Theſe are moſtly herbaceous plants, ſome annual but more perennial, and ſome of the ſpecies ſuffruticoſe, or woody at the bottom of the ſtems, which in ſome are proſtrate, in others upright. Leaves alternate. Flowers either ſolitary and axillary with two ſmall bractes, or in looſe terminating ſpikes with three little bractes. L. lactefcens and minuta (n 25. 30.) have no bractes. L. longiflora has a very long tubular flower, with a bifid ſtigma [a]. L. Phyteuma, bulboſa, volubilis and lutea have the anthers diſtinct. The predominant colour in the corollas is blue.

1. This is a ſmall annual plant, ſcarcely a hand in height, herbaceous, upright, ſimple, ſmooth and even. Leaves alternate, ſeſſile, remote, acute, even, paculous. Peduncles axillary, one-flowered, naked, even, upright, twice as long as the leaves. Capſule inferior, turbinate. Native of the Cape of Good Hope [b].

L. debilis of the ſupplement is doubtleſs the ſame with this. It is there ſaid to be a very little plant, ſo much reſembling L. depreſſa (n. 41.) as to be perhaps only a variety of it; and to have been obſerved at the Cape by Thunberg.

2. Branch or ſtem ſomewhat woody, angular, tomentoſe-mealy, eſpecially towards the top, leafy. Leaves ſcattered, oval-oblong, netted-veined, very thickly tomentoſe underneath, with the veins thick and ſtanding out. Leaves quite entire at the edge, but being rolled back, Linnæus miſtook the interſtices between the veins for notches, and ſet them down as crenate in the ſpecific character. Petiole channelled, mealy. Flowers axillary, ſolitary, peduncled. Calyx mealy, hemiſpherical, ten-angled, five-toothed; teeth linear, upright, preſſed cloſe to the corolla. Corolla curved in, bellying a little in the middle, five-cornered, the ſegments of the border unequal, linear, mealy on the outſide. Stamens a little longer than the corolla. Anthers united into an oblique incurved ſmooth cylinder, bearded at top below the ſtigma. Style a little longer than the ſtamens. Capſule four-valved; valves bowed back, ſmooth. Native of New Granada, where it was found by Mutis. Linneus ſuſpected a great affinity between this plant and Columnea ſcandens [c]; and has given the differences in the ſupplement.

3. This is an annual plant, about a hand in height, upright, hiſpid and leafy below, divided at top into a longer panicle. Leaves blunt, pubeſcent underneath. Panicle ſmooth and even, with the leaves of the ramifications awl-ſhaped. The lower peduncles are longer. Found at the Cape of Good Hope by Thunberg [d]. Both in the Syſtema and Supplementum it is by miſtake named bellidiflora.

4. This is a ſhrubby, upright, branched plant, the branches ſurrounded with abundance of narrow ſharp leaves an inch in length. Flowers many, ſmall, blue, at the tops of the twigs, among the leaves [e]. The calycine leaflets have a gland at their baſe.

Native of the Cape of Good Hope [f]. Introduced in 1786, by Mr. Francis Maſſon [g].

5. The root conſiſts of numerous capillary whitiſh fibres. Leaves growing at the bottom of the water in a circle, numerous, about two inches long, reflected into an elegant curve at the end, ſmooth, conſiſting of two hollow parallel tubes. Stem erect, round, hollow, ſmooth, from twelve to eighteen inches high, naked except three or four oval ſeſſile ſcales about a quarter of an inch long. Flowers about nine in a looſe ſpike, above the water, from half an inch to an inch aſunder, on ſlender peduncles about half an inch long, each ariſing from a bracteal ſcale ſimilar to thoſe on the ſtems. Calyx divided into five linear or awl-ſhaped ſegments, a line and half or two lines long. Corolla white faintly tinged with blue: tube narrow: upper lip of two narrow lanceolate ſegments, erect; lower of three oval reflected ſegments, the middle one larger and longer. Capſule elliptical, ſurrounded with the calyx, forming a ring a little beneath the ſummit, and terminated by the ſtyle with its club-ſhaped hairy ſtigma [h]. Linnæus remarks that the whole plant, even the leaves beneath the water, are milky: and that the flowering-ſtalk is of a length proportional to the depth of the water in which the plant grows.

Native of the north of Europe; in lakes of mountainous countries. With us in Wales, Weſtmoreland, Cumberland, Scotland. It flowers in july and auguſt.

It was ſent to Chuſius by Dortmann an apothecary at Groeningen, hence he named it Gladiolus ſtagnalis Dortmanni, and Rudbeck called it Dortmanna.

6. The root and herb of this ſpecies are a violent poiſon.

Native of Peru [i].

7. A foot high, with a round ſtem, ſcarcely branched. Leaves linear-lanceolate below, linear above, quite entire, bluntiſh, naked, ſeſſile. Flowers in a looſe raceme, ſolitary on alternate peduncles, from the axils of the upper leaves, furniſhed with a leaflet. Corollas blue. It is an annual plant, and a native of Canada, where it was found by Kalm [k].

8. Native of the Cape of Good Hope.

9. Leaves very large, repand, petioled. Flowers many in corymbs, interſperſed with rounded hiſpid bractes. Pedicels elongated, hiſpid. Calyx hiſpid, with ovate, blunt ſegments. Corolla club-ſhaped, ferruginous, before flowering curved, afterwards ſtraight. Stamens red hiſpid.

Native of South America, where it was found by Mutis.

10. This differs from the preceding in the ferruginous nap with which the ſtems, petioles, nerves of the leaves, peduncles, calyx and corolla are covered; in having the leaves much ſmaller, acute and ſerrate; the peduncles more elongated, almoſt the length of the leaves; the flowers more curved; and the genitals elongated far beyond the corolla, not included in it.

Native of America, found by Mutis.

The hairineſs in this and L. Columnea is ſingular, parts of the herb and flower being quite concealed by it [l].

[a] Jaſeq. [b] Linn. mant.
[c] Smith. [d] Linn. ſuppl. [e] Burm. ſuppl. [f] Linn.
[g] Hort. kew. [h] Woodw. Mſ. [i] Linn. from Feuillée.
[k] Linn. ſpec. [l] Linn. ſuppl.

11. Stem herbaceous, filiform, annual, procumbent, creeping; with upright branches, five inches in length. Leaves alternate, ſmooth, ſeſſile. Flowers peduncled, ſolitary, terminating. Calycine ſegments ſhort, awl-ſhaped, interrupted, patulous. Corolla pale blue. Stigma bifid, revolute. Capſule two-celled. Seeds roundiſh.—It differs both from L. zeylanica and erinoides in having the leaves quite entire and the peduncles terminating; though it is like them in habit.

Native of China near Canton [a].

12. Native of Cayenne. Diſtinguiſhed and named from the great length of the ſtamens. Linneus ſays that he ſaw the plant in Royen's collection, and we are no otherwiſe acquainted with it.

13. Native of the Cape of Good Hope.

14. This reſembles L. coronopifolia (n. 40.) very much [b]. The filaments are connate at the baſe; the anthers diſtinct; and the petals equal. Hence Bergius ſeparated it from Lobelia under the name of *Cyphia* [c].

15. This is an annual plant. Stems herbaceous, a foot high. Leaves alternate, ſeſſile, narrow-lanceolate, and as it were glued together at the baſe: the upper ones leſs remote. Raceme peduncled, upright; with the peduncle obſoletely three-cornered in moſt. Flowers blue.

Native of the Cape of Good Hope [d]. Introduced in 1774, by Mr. Francis Maſſon. It flowers from may to ſeptember [e].

16. This is an annual, herbaceous elegant plant, ſeldom above fourteen or ſixteen inches in height, the whole of it rough-haired. Stem almoſt upright, very much branched from all the axils. Leaves alternate, ſeſſile, ſubpinnatifid-toothed, ſharpiſh, ſmooth, half a foot long. Peduncles one-flowered, axillary, ſolitary, villoſe. Bracte awl-ſhaped. Calyx truncated, with five diſtant, toothletted teeth. Corolla handſome, upright, white, four inches long: tube the length of the leaf, filiform; border equal. Filaments joined to the tube of the corolla almoſt to the top. Anther ten-grooved. Germ turbinate, five-cornered. Stigma fleſhy, two-lipped. Capſule green, when it burſts at the ripening of the ſeeds. The whole plant is very poiſonous. Taken internally it brings on an invincible purging. If the plant be handled, and the hand be unawares applied to the eyes or lips, it brings on an inflammation. Horſes are reported to burſt with eating it; whence in the Spaniſh Weſt Indies it has the name of *Reventa-cavallos*. It is well known in Domingo under the name of *Quedet* [f]. It is alſo native of Jamaica, Cuba, Martinico, by rivulets, and in moiſt, cool, ſhady places.—Cultivated in 1739, by Mr. Miller. It flowers from june to auguſt [g].

17. This is very diſtinct from L. hirſuta (n. 39.)

Native of the Cape of Good Hope, where it was found by Thunberg.

18. This ſpecies is ſingular in having the branches flowering almoſt from the baſe in all the axils of the leaves, and the flowers all nodding to one ſide. Found at the Cape by Thunberg [h].

19. Root perennial. Stem herbaceous, three or four feet high, ſimple or only ſimply divided at top, angular, thick, ſmooth, red, milky. Leaves ſubſeſſile, or on very ſhort petioles, ovate-lanceolate, a foot long, alternate, nerved, ſmooth on both ſides: toothleſs at the baſe of the leaf linear. Petioles very ſhort, decurrent at the ſides, whence the ſtem is winged, continued under the leaf to the tip, thick, red. Raceme almoſt upright; curved. Flowers numerous, heaped, blood-red, very large, pubeſcent, on round peduncles an inch in length, with linear bractes at the baſe of them. Calyx ſuperior, with five long lanceolate reflex ſerrate teeth. Corolla curved inwards. The anther has five blue grooves. Germ inferior, angular, ſurrounded by the calyx. Style thick. Stigma incloſed within the anther, capitate-compreſſed, white-villoſe. Capſule angular, two-celled, crowned by the calyx [i].

[a] Loureiro. [b] Linn. ſuppl. [c] Linn. mant. & Berg. cap. [d] Linn. mant. [e] Hort. kew. [f] Jacquin, Linn. mant. Browne. [g] Hort kew. [h] Linn. ſuppl. [i] Swartz.

Native of Jamaica, in the cooler mountains, where it ſhoots frequently to the height of five or ſix feet [a]. Introduced in 1787, by Mr. Alexander Anderſon [b].

20. Found by Thunberg at the Cape of Good Hope. In the ſupplement, it is ſaid to be ſingular that it ſeldom has leaves or flowers.

21. This ſeldom riſes above three feet in height. It grows generally in the lower ſhady hills of Jamaica [c]. —Sloane ſays it has a ſtalk as big as one's finger, green and ſmooth. Leaves many, without order, ten inches long, and two broad in the middle, dark green. Flowers pale yellow. Seeds very ſmall, brown.

22. Native of the iſland of Guadeloupe [d].]

23. The root is compoſed of many white fleſhy fibres. The lower leaves are oblong, and of a dark purpliſh colour on their upper ſide. The ſtalks are erect, about a foot and half high, with leaves about three inches long, and an inch and half broad in the middle, on very ſhort petioles and placed alternately. The ſtalk is terminated by a ſpike (raceme) of flowers, of an exceeding beautiful ſcarlet colour. They have a pretty long tube, which is a little incurved, and at the top they are cut longitudinally into five ſegments; two upper, which are the ſmalleſt, are greatly reflexed; the three under, which form the lower lip, are longer, and ſpread open. They appear at the end of july and in auguſt, when they make a fine appearance for a month or more, and when the autumn proves favourable, they will produce good ſeeds here. It grows naturally by the ſide of rivers and ditches in great part of North America. [Linneus and the Kew Catalogue aſſign it to Virginia only. Parkinſon, who mentions it as cheriſhed in our gardens (in 1629), ſays, "that "it groweth near the rivet of Canada, where the "French plantation in America is ſeated."]

24. Root perennial. Stem ſimple, from a foot to two feet in height, and upwards, ſtrong, ſimple, ſmooth, with angles formed by the decurrent edges of the leaves having ſtiffiſh hairs on them. Leaves alternate, ſeſſile, ſomewhat rugged. Flowers axillary, ſolitary, numerous, large, on ſhort peduncles, forming altogether a long ſpike. Calyx ſerrate-toothed; the ſegments lanceolate, covering the germ, as in Campanula Medium, &c. Corolla blue, varying in ſhades from a rich violet to pale blue, angular: the ſegments almoſt equal, ciliated along the keel, and having two bumps on the palate [e]. Capſule united with the calyx to the middle, ſubglobular, mucronate, marked with a ſlight groove on both ſides, two-celled, two-valved: partition contrary to the valves. Receptacle ſpongy, excavated, conical, convex on one ſide, faſtened on the other to the middle of the partition on both ſides. Seeds numerous, ſmall, ovate-oblong, wrinkled, of a reddiſh yellow colour [f].

Native of Virginia. Cultivated here in 1665, as appears from Rea's Flora [g]. It flowers from auguſt to octobers; or according to Mr. Miller] earlier than the preceding, and the ſeeds frequently ripen in England.

[Every part of the plant abounds with a milky juice, and has a rank ſmell. The root, which is the part directed for medicinal uſe, in taſte reſembles tobacco, and is apt to excite vomiting. It derives the trivial name from its efficacy in the cure of ſyphilis, as experienced by the North American Indians, with whom it was a ſecret. Sir William Johnſon purchaſed the ſecret, and it has ſince been publiſhed by Kalm, Bartram, &c.

The method of employing this medicine is as follows. A decoction is made of a handful of the roots in three meaſures of water. Of this, half a meaſure is taken in the morning faſting, and repeated in the evening: the doſe is gradually increaſed till its purgative effects become too violent, when it is to be intermitted for a day or two, and then renewed till a perfect cure is effected. During the uſe of this medicine a proper regimen is enjoined, and the ulcers are alſo to be frequently waſhed with the decoction, or if deep and foul, to be ſprinkled with the powder of the inner

bark

bark of New-Jersey Tea-tree (Ceanothus americanus). Although the plant is said to cure the disease in a very short time, yet its virtues have not been confirmed by any instances of European practice [a].

25. This species is a native of the island of St. Helena. It is probably the same with L. arborea of Forster, found in the Society isles.

26. Leaves alternate, subpetioled, acute, very finely serrate. Peduncles the length of the leaves, with two linear bractes towards the base. Calyx gibbous, with linear-lanceolate segments. Corolla the length of the leaf, five-cornered, impressed in five rows above the base. Capsule ventricose [b].

L. levigata, which is the same with this, is thus described in the Supplement. Stem herbaceous, smooth, round. Leaves alternate, petioled, elliptic or ovate-lanceolate, acute, smooth, serrate. Peduncles lateral, axillary, round, with two awl-shaped bractes at the base. Calyx superior, with five, awl-shaped, patulous teeth. Corolla oblong, tubular, incurved, red, with a cavity at the base within and below the stamens: border short, five-cleft: the two upper segments acute, the three lower shorter. Stamens longer than the corolla. Capsule globular, crowned with the calyx, two-celled. Seeds minute.

Native of the West Indies. Introduced in 1786, by Mr. Alexander Anderson. It flowers in april [c].

27. This is a biennial plant in England. Stems channelled, hairy, two feet high. Leaves about two inches long, and one broad in the middle, sessile, light green. Flowers small, on long, slender, axillary peduncles, forming a loose spike. Corolla light blue. It flowers in july, and the seeds ripen in september.

[Native of Virginia and Canada. Cultivated by Mr. Miller in 1759 [d].]

28. This is an annual plant. The stem rises about a foot high, and then divides into four or five smaller, which grow erect. The lower part has heart-shaped smooth leaves, an inch and half long, and three quarters of an inch broad at the base, lessening to a point at the end, on short petioles. The upper slender stems are thinly furnished with small purplish flowers to the top.

[The peduncles are long and somewhat angular [e]. It is a native of America. Linnæus says of Virginia and Canada: but Mr. Miller gives it to Jamaica, whence Dr. Houstoun sent him the seeds. He cultivated it in 1739 [f].]

29. This is an annual plant. Stem nearly upright, somewhat curved, from twelve to eighteen inches high, simple, smooth, angular; the angles rough. Lower leaves elliptical, blunt, two inches long, from six to eight lines broad, irregularly and slightly toothed, petioled: the next above sessile; the upper lanceolate, half embracing, closely pressed to the stem at the base, frequently having a bundle of small leaves in the axils, appearing like the rudiments of branches; all smooth. Flowers in a long spike, sometimes more than twenty; the lower ones distant, the upper rather crowded, each on a short peduncle, from the axil of a bracteal leaf; of which the lower ones are lanceolate, the upper awl-shaped. Calyx deeply divided into five awl-shaped erect segments, three lines long. Corolla about half an inch long, rough, bright blue; tube narrow; upper lip with two awl-shaped erect segments; lower with three lanceolate reflected, the middle one longest. Stamens longer than the tube. Anthers forming a cylinder, deep blue with white hairy margins. Style slender. Stigma club-shaped, hairy, inclosed within the cylinder of anthers [g].

The whole plant is milky, of a warm taste, and if chewed, especially the root, excites a pungent sense of burning in the tongue [h].

Native of France, Spain and England. On Shute common between Axminster and Honiton, Mr. Newbery. It flowers in july and august.

30. This is a minute annual plant, like Cineraria and Bellium, only about an inch high. Root filiform, creeping by runners. Leaves radical, obovate, obtuse, tender, scarcely crenate, on long petioles. Scape setaceous, two inches high, upright, one-flowered. Calyx oblong, lanceolate, almost upright. Corolla funnel-form. Capsule inferior, oblong. It is allied to L. Laurentia, but is more tender, without any bractes on the scape. It differs from L. Erinus in having no stem but the scape or naked flowering stalk [i].

Native of the Cape of Good Hope. Introduced in 1772, by Mons. Richard. It flowers from june to september [k].

31. Stem filiform, contrary, herbaceous. Leaves alternate, remote, even, linear, with obsolete subcalloose toothlets; at top frequently trifid, the lateral segments very short. Flowers lateral, solitary, pedunculed. Anthers distinct.

Native of the Cape of Good Hope, where it was found both by Sparrmann and Thunberg [l].

32. This is seldom more than three or four inches high. The leaves resemble those of the common Daisy in shape and size. The flowers come out singly on very long slender peduncles [a]: with a setaceous bractle on the middle of each [b].

Native of Italy, about Pisa. In the island of Elba, Corsica and Sicily.

Micheli made this a distinct genus under the name of Laurentia, in compliment to Marcantonio Laurenti, M.D. and Professor at Bologna.

33. Native of New Zealand [c].

34. This is an annual plant. Stem a span high, filiform, branched and spreading out at bottom. Root-leaves oval; stem-leaves lanceolate; all smooth. Peduncles axillary, naked, three times as long as the leaves, slender, one-flowered [d]. Flowers small and blue, appearing in july; succeeded by small roundish seed-vessels, filled with small seeds which ripen in september.

Native of the Cape of Good Hope. [Cultivated by Mr. Miller in 1759. Said in the Kew catalogue to have been introduced by Mr. Masson in 1774.

35. This also is an annual plant, with many slender, trailing, herbaceous, simple stems, half a foot long. Leaves alternate, subpetioled, remote, bluntish, with two or three obsolete lateral teeth. Peduncles lateral, solitary, shorter than the leaf. Calycine leaflets lanceolate. Corolla funnel-form-lanceolate, angular, equal, blue, with patulous segments. Filaments united into a five-streaked, club-shaped tube. Anthers with distant tips. Germ inferior. Stigma two-lipped hirsute. Capsule obovate, two-celled.

Native of the Cape of Good Hope [e]. Cultivated by Mr. Miller in 1759. Said in the Kew Catalogue to have been introduced by Mr. Masson in 1786.

36. Root annual. Root-leaves petioled, obovate. Stem quite simple, a span high, even. Stem-leaves alternate, even, scarcely toothed, remote. Flowers from the upper axils of the leaves, pedunculed, solitary, small, blue. It may perhaps be a variety of the preceding [f].

Native of the East Indies.

37. Native of the Cape of Good Hope, where it was found by Mr. W. Paterson. Introduced in 1780, by the Countess of Strathmore. It flowers from may to august [g].

38. This is a small plant, that has the appearance of Veronica Chamædrys. Stem creeping. Leaves alternate, petioled, almost smooth: lower obtuse, crenate; upper acute, sharply serrate. Peduncles axillary, subsolitary, longer than the leaf, pubescent [h].

Stem round. Leaves cordate, smooth, petioled. Flowers blue.

Native of China, in watery and shady places [i].

39. Stem quite simple, upright, striated. Leaves alternate, sessile, upright, with a few acuminate upright serratures. Flowers terminating, yellow, larger than the leaf. Filaments connate. Anthers erect, striated, distinct, bearded at the tip. Style also bearded at the tip. Stigma oblong, bifid, revolute [k].

[a] Woodville. [b] Linn. spec. [c] Hort. kew. [d] Ibid. [e] Linn. [f] Hort. kew. [g] Woodward, MS. [h] Willdr. from Bocc. & Mor.

Native of the Cape of Good Hope. Introduced in 1774, by Mr. Francis Maſſon. It flowers in june and july [1].

40. Found at the Cape of Good Hope by Thunberg [2].

41. Stem procumbent, hairy. Leaves linear, with three teeth on each ſide. Peduncles longer than the whole plant [3]. Native of the Cape of Good Hope. Introduced in 1787 by Mr. Francis Maſſon. It flowers in july and auguſt [4].

42. Stem herbaceous, a hand long, varicoſe, proſtrate on every ſide. Peduncles alternate, the length of the leaves, ſolitary. Leaves not at all decurrent. Flowers dark-purple. Native of the Cape of Good Hope [5].

Thunberg has ſeveral other ſpecies, and has enumerated thirty Lobelias natives of the Cape of Good Hope, in his Prodromus Plantarum Capenſium, p. 39, 40.

Miller has only one ſpecies of Lobelia, which is the Scævola of Linnæus. His Rapuntiums belong to this genus. He enumerated ten in the ſeventh edition of his Dictionary. In the eighth he omitted the ſecond ſpecies, which is only a variety of the firſt, but preſerved the ten deſcriptions, ſo that the numbers do not correſpond, but the deſcription of the third ſort belongs to n. 2. and ſo of the reſt. This error is rectified in the quarto edition of 1771.

The following ſynopſis, though incomplete, may aſſiſt in diſcriminating the ſpecies.

Herbaceous.

PROPAGATION AND CULTURE.

16. The ſeeds of this ſort ſhould be ſown after it is ripe, in pots filled with rich earth, and plunged into the tan-bed in the ſtove, obſerving to refreſh the earth frequently with water. In the ſpring theſe pots may be removed, and plunged into a hot-bed, which will ſoon bring up the plants: when theſe are fit to remove, they ſhould be each tranſplanted into a ſeparate ſmall pot filled with rich earth, and plunged into a freſh hot-bed, ſhading them from the ſun till they have taken new root; then they may be treated in the ſame way as other tender plants from the ſame country, giving them a large ſhare of air in warm weather, and frequently refreſhing them with water. In autumn the plants muſt be plunged into the tan-bed of the ſtove, where they will flower the following ſummer, and produce ripe ſeeds, ſoon after which the plants will decay. If the ſeeds of this plant are brought from the Weſt-Indies, they ſhould be ſown as ſoon as they arrive, in pots filled with rich earth; and if it happens in the winter, the pots ſhould be plunged into the tan-bed in the ſtove; but if it is in the ſpring or ſummer, they may be plunged into a hot-bed in the common frames. Theſe ſeeds when ſown in the ſpring, ſeldom grow the ſame year, therefore the following autumn the pots ſhould be removed into the ſtove, and managed according to the above directions.

23, 24. Theſe are propagated by ſeeds, which, when they ripen in England, ſhould be ſown in autumn in pots filled with rich kitchen-garden earth, and placed under a common hot-bed frame, or, if the ſeeds come from the country where the plants grow naturally, they ſhould be ſown in the ſame way as ſoon as they arrive, for if they are kept out of the ground till ſpring, they will lie a year in the ground before they vegetate. The pots in which theſe ſeeds are ſown ſhould be expoſed to the open air at all times when the weather is mild, but they muſt be ſcreened from the froſt, and the very hard rain in winter. In the ſpring the plants will appear, when they ſhould have as much free air as poſſible in mild weather, and if the ſpring proves dry, they muſt be frequently refreſhed with water. As ſoon as they are fit to remove, they ſhould be each planted in a ſeparate ſmall pot filled with the ſame rich earth, and placed in the ſhade till they have taken new root; then they may be placed where they may have the morning ſun, in which ſituation they may remain till autumn. During the ſummer, they muſt be duly watered in dry weather, and when the roots have filled the pots, they ſhould be removed into larger. In autumn they muſt be placed under a common frame to ſcreen them from hard froſt, but they ſhould enjoy the open air at all times when the weather is mild. The ſpring following they ſhould be new potted, and placed where they may have the morning ſun, always obſerving to water them duly in dry weather, which will cauſe their ſtalks to be ſtronger, and produce larger ſpikes of flowers in auguſt. Theſe will continue long in beauty, if they are not too much expoſed to the ſun, and, if the autumn proves warm, the ſeeds will ripen well in England. The roots will ſometimes laſt two or three years, and produce offsets for increaſe, but they will not flower ſo ſtrong as the ſeedling plants, therefore an annual ſupply of them ſhould be raiſed. There are many who propagate them by cutting their ſtalks into proper lengths, and plant them in pots filled with good earth, or into an eaſt border, covering them cloſe with glaſſes. Theſe frequently take root, but they are not ſo good as the ſeedlings.

They will live in the full ground if they are protected from hard froſt in winter, and they will flower ſtronger than thoſe in pots.

27. Sow the ſeeds in autumn in pots filled with rich earth, and treat the plants in the ſame way as the twenty-third ſort.

28. When the ſeeds are permitted to ſcatter on pots which ſtand near them, and theſe are ſheltered from froſt, the plants will come up plentifully the following ſpring; or if they be ſown in pots in autumn, and ſheltered in winter, the plants will riſe the following ſpring. Tranſplant theſe into ſeparate ſmall pots, and place them under a frame.

29. Sow the ſeeds in autumn in a warm border, or in pots filled with loamy earth, and placed under a common frame in winter. When they come up in the ſpring, tranſplant them into a border of ſoft loamy earth, or into other pots, ſhading them till they have

[1] Hort. kew. [2] Linn. ſuppl. [3] Linn. mant. [4] Hort. kew. [5] Linn. ſuppl.

taken new root, and duly watering them in dry weather, which will cauſe them to flower ſtrong, and produce good ſeeds annually.

34. 35. If the ſeeds of theſe ſorts be ſown in autumn, they will ſucceed much better than when they are ſown in ſpring: theſe may be ſown in pots, and ſheltered under a common hot-bed frame in winter, expoſing them to the open air at all times in mild weather, but ſereening them from the froſt; and in the ſpring, the pots ſhould be plunged into a moderate hot-bed, which will ſoon bring up the plants; when theſe are fit to remove, they ſhould be each planted in a ſeparate ſmall pot filled with rich earth, and plunged into a moderate hot-bed again, ſhading them from the ſun till they have taken new root; when they muſt have a large ſhare of air at all times when the weather is mild, and as the plants grow ſtrong, they ſhould be gradually hardened to bear the open air, into which they ſhould be removed in June, placing them in a ſheltered ſituation, where they will flower in July, and if the ſeaſon prove favourable, the ſeeds will ripen in September; but if the ſeaſon ſhould prove cold, it will be proper to remove one or two plants into a glaſs caſe, to obtain good ſeeds.

[N. 5. 7. 23. 24. 27. 29. 32. being natives of Europe or North America, are hardy plants, and directions for their treatment are given under 23. 27. and 29.

N. 1. 3. 4. 8. 13. 14. 15. 17. 18. 20. 30. 31. 34. 35. 37. 39. 40. 41. 42. are natives of the Cape of Good Hope. Theſe, therefore, muſt be preſerved in the dry ſtove, and treated as directed for N. 34.

The reſt being natives of the Weſt Indies, and other hot climates, muſt be preſerved in the bark ſtove, and treated as directed above for N. 16.

DESCRIPTION, *&c.*

Root annual. Leaves oppoſite, mucronate. Branches proſtrate, alternate, pubeſcent, clammy. It has the appearance of Scleranthus[a]. Capſule ſmall, narrower above. Receptacle columnar, looſe, pencil-branched above, almoſt the length of the capſule. Seeds ſixteen to twenty, very ſmall, ovate produced into a beak, with a very ſlight groove along the back, hollow-dotted, ſtraw-coloured or rufeſcent[b]. Native of Spain, on open hills.—Introduced in 1770, by Monſ. Richard. It flowers in June[c].

Cavanilles ſays, that the ſtems are a ſpan high, ſubdichotomous. Leaves very ſmall, with ſtipulaceous appendages, toothletted below. Flowers ſolitary, axillary, and in the diviſions of the branches. Calycine leaflets mucronate, wider at the baſe, concave; the three outer two-awned below, the two inner almoſt always awnleſs. Corolla white; petals obovate, emarginate. Filaments ſhorter than the corolla. Anthers ovate, twin. Germ ovate-acuminate. Stigmas three. Capſule ovate-acute.

DESCRIPTION, *&c.*

Stem upright, obſoletely quadrangular, brachiate. Leaves oppoſite, lanceolate-ovate, acutely ſerrate. Branches oppoſite: laſt branchlets imbricate, with ſubcordate, embracing, ſerrate, ciliate leaflets; the lower ones ſmaller, the upper ones more crowded, and gradually larger, till a branchlet terminates in a ſtoriferous head[a]. Capſule ſmall, clothed with the calyx, obovate or turbinate, thin, whitiſh, opening three ways at top. In each cell one or two ſeeds, faſtened to the inner angle, oblong, convex on one ſide, obſoletely angular on the other, of a pale rufeſcent colour, with abrupt tranſverſe lines of a deeper colour diſpoſed longitudinally in rows; covered with a ſingle membranaceous ſkin that diſſolves in water into a pellucid mucilage[b].

Found at La Vera Cruz in South America by Houſtoun.

DESCRIPTIONS, &c.

1. Root perennial, creeping. Stems ſeveral from the ſame root, proſtrate or oblique at the baſe, but the flowering ſtem upright, ſmooth, from ſix inches to eighteen, twenty and twenty-four inches in height, according to the ſoil: they have ſeveral joints near the baſe, at a ſmall diſtance from each other, but on the upper part only one or two. (Auguſt the 2d, 1797, I count, on a great number of plants of a middling ſize three joints, and never more than four, the flowering-ſtem running up from eleven to fourteen inches above the laſt joint.) They are frequently ruſſet-coloured at the joints. Leaves four or five inches long, and from two to four lines wide, lengthened out into a point; the leaf on the ſtem above twice as broad as thoſe next the root and on the runners. The ſheath covers the ſtem for ſeveral inches above the upper joint; both that and the leaves are ſmooth. The flowers are in a ſpike, which is from four to ſix or ſeven, and even nine inches in length, compoſed of many (ten to eighteen) ſpikelets, ranged at a little diſtance from each other, in two rows alternately along the rachis or common receptacle. The ſpike is generally flat, but ſometimes nearly cylindrical; and it ſometimes ſhows a diſpoſition to become branched, particularly towards the bottom. The rachis is flexuoſe, or changes its direction in a curve line from one ſpikelet to another; and each ſpikelet being lodged at the baſe in a hollow of it, has no occaſion for an inner valve to the calyx for protection, and therefore is not provided with one. The number of flowers in each ſpikelet varies from three or four to ſix, ſeven or eight, and even ſometimes nine, ten and eleven; but ſix or ſeven is the moſt common number. The valve of the calyx tapers to a point; and the terminating calyx is two-leaved. The two inner huſks, which are the valves of the corolla, are both of the ſame length, or nearly ſo. The germ is placed between the upper of theſe, and two ſmall white ſemitranſparent ſubſtances, which Linnæus calls the nectaries. The ſeed eaſily quits the chaff.

There are many varieties of this Graſs, differing in ſize or colour of the ſtem and ſpike, as well as the number of flowers in each ſpikelet. The flowers are now and then found with awns or beards. The ſpikelets alſo are ſometimes cluſtered, and ſometimes branched.

Perennial Darnel is common in moſt parts of Europe, by way ſides and in paſtures, flowering in june. It is called in Engliſh *Ray-graſs*, from the French *ivraie*, which is their name for L. temulentum, and they call this *Fauſſe ivraie*. It is corruptly called by farmers Rie-graſs, but this Graſs bears no reſemblance to Rie, and that is a name appropriate to a very different Graſs, *Hordeum pratenſe*. Mr. Ray names our Ray-graſs *Red Darnel-graſs*. In ſome places it is called *Crop*, in Devonſhire, *Eaver*, in Norfolk, *White Noneſuch*. In German it has many names; *Perennirende* or *dauernde Lolch*, *Winterlolch*, *Suſſer Lolch*, *Engliſche Raygras*, *Lethe*, *Lethegras*, *Dort*, *Dorten*, *Drot*, *Wintertriſpe*, *Mauſtertſte*, *Mauſthafer*, *Rothhafer*, *Furſthafer*, *Maulkorn*, *Peterſhorn*, *Taubkorn*, *Wilder Dinkel*, *Dinkelſpelzen*, *Grashauch*, *Grashalch*, *Tanſch*, *Teiver*. In Daniſh, *Raigræs*. In Swediſh, *Renrepe*, *Engelmanz Rifegras*. In Italian, *Loglio vivace*, *Loglio ſalvatico*, *Fenice*. In Spaniſh, *Ballico*, *Vallito*. In Portugueze, *Joyo vivace*. In Ruſſian, *Pſchanez*.

How long Ray-graſs may have been in cultivation, I am not able to aſcertain. We may, however, venture to fix the introduction of it after the middle of the laſt century. For not only Gerarde in 1597, his republiſher Johnſon in 1633, and Parkinſon in 1640, give not the leaſt hint of any uſe to which this graſs is applied, but none of the writers on huſbandry before the Reſtoration, as Sir Hugh Plat, Googe, Markham, Sir Richard Weſton, Hartlib, Gabriel Plattes, Blith or Yarranton, ſay a word in its commendation, or even

insinuate that this, or any particular species of Grass, properly so called, was sown in laying down land.

The first mention I find made of it for cultivation, is in Dr. Plot's Oxfordshire, printed in 1677[a]. "They have *lately* sown, says he, *Ray-grass*, or the *Gramen loliaceum*, by which they improve any cold, sour, clay-weeping ground, for which it is best, but good also for drier upland grounds, especially light stony or sandy land, which is unfit for lasher loin. It was first sown in the Chiltern parts of Oxfordshire, and since brought nearer Oxford by one Mr. Eustace, an ingenious husbandman of Islip, who, though at first laughed at, has since been followed even by those very persons that scorned his experiment; it having precedence of all other grasses, in that it takes almost in all sorts of poor land, endures the drought of summer best, and in the spring is the earliest grass of any, and cannot at that time be overstocked, its being kept down making it sweeter and better beloved by cattle than any other grass: nay sometimes they have been known to leave meadow hay to feed on this: but of all other cattle it is best for horses, it being hard hay; and for sheep, if unsound, it having been known by experience to have worked good cures on them, and in other respects the best winter grass that grows." Some, he informs us, sow two bushels on an acre, but it is best to sow three, with Non-such.

Ray, in his history (1688) relates, that it is sown in a few places, and that it is excellent for fatting bullocks. In the third volume of the Oxford history of Plants by Morison and Bobart (1699) it is said, that the seeds are gathered and sown in thin and moist land; and that it is much esteemed, under the name of Ray-grass, as food for sheep and other cattle.

According to Stillingfleet, "it makes a most excellent turf on sound rich land, where it will remain. Many, he adds, are tempted by the facility of procuring the seed of this grass to lay down grounds near their houses, where they want to have a fine turf with it; for which purpose, unless the soil be very rich, a worse grass cannot be sown, as it will certainly die off in a very few years entirely." This gentleman thinks that Ray-grass does not feed good venison, and presumes from hence that it is not proper for sheep, having always observed that the same kind of ground which yields good venison, yields also good mutton. If it be the natural produce of very strong or wet lands, this is easily accounted for. In such situations it is by no means unprolific of leaves, but in dry upland pastures it runs much to stalks or bents. It is not well adapted to form a lawn, its foliage being of quick growth, and its flowering stems continually shooting forth[b]. [Mr. Miller says[c], that Ray-grass will succeed better than any other sort in strong cold land, and is an earlier seed in the spring; but that it is a very coarse grass, becoming very hard and wiry unless it be cut early, so that few cattle care to eat it. He remarks, that it has few leaves, and runs much to stalk or bents, or as it is called in some counties Bennet. When this grass is fed, therefore, he recommends the bents to be mown off. He adds, that there is another species (variety) called Red Darnel, which is of a worse nature than the other; the stalks growing hard much sooner, and having narrower leaves. It is very common in most pasture grounds, for as it comes early to flower, the seeds are generally ripe before the hay is cut. [This variety is the produce chiefly of dry pastures, where Ray-grass certainly produces little else besides stalks.

After all the encomiums that have been bestowed upon this grass, Dr. Anderson asserts that it is now in general known to be but a very indifferent grass for pasture, on account of the tendency it has to send out numerous seed-stalks very early in the season, after which no animal will taste it; so that unless it be for a very short while in the spring, when the leaves are tender and succulent, it is no longer fit for pasturage: the stalks after the month of may becoming withered; so that after that period, the field is usually covered entirely with these dead stalks, and remains during the rest of the season with very few signs of vegetation. It is moreover but a short-lived grass, usually dying out entirely in five or six years. On both which accounts, it is by no means to be recommended in general as a proper grass for pasturage.

All grasses that run chiefly to seed-stalks, should seem to be, for the same reasons, improper for that purpose; so that our researches ought to be directed principally to discover such grasses as run chiefly to leaves, and produce but few flower-stalks.

It was this quality that first recommended to Dr. Anderson the *Purple Fescue-grass*, and induced him to try some experiments with regard to it[d].

It is judiciously remarked by Mr. Curtis, that though, *Lolium perenne* may not possess all that is desirable in a grass, it is not therefore to be considered as of no value, and indiscriminately rejected. The complaint so generally urged against it, of its producing little more than stalks or bents, will be only found valid when the plant grows in upland pasture: in rich moist meadows its foliage is more abundant, and it seems to be the general opinion of agriculturists that it is highly acceptable and nutritious to cattle[e]. Certainly it is not adapted to all soils and situations equally. Several sorts may be even preferable to it, and though early, it is not the first that springs, not only the vernal, but the Fox-tail and the Meadow-grasses, all excellent in their kind, appearing earlier than this[f]. Ray-grass, however, is still valuable both as an early seed, and as being fit to mow for hay a fortnight before mixt grasses. For the latter use the abundance of stalks is an excellence, provided the grass be cut whilst the sap is in them, the chief nutriment of hay residing in these.

Mr. Swayne having hinted in his *Gramina pascua*, a work very useful to gentlemen and farmers in distinguishing pasture grasses, that there was reason to think that Ray-grass had by frequent sowing degenerated, so as to be inferior in many respects to that which grows naturally in our best meadows. Mr. Pacey, an enlightened agriculturist in the upper part of the county of Stafford, has raised it from seed selected from old pastures, and has multiplied it to that extent as to sell annually a considerable quantity; it having been proved by the most competent judges to be greatly superior to the Ray-grass commonly cultivated[g]. Mr. Swayne asks whether the L. temulentum has had any share in bringing on this degeneracy? I should think not, but ascribe it rather to cultivating and saving the seed on improper soils, particularly such as are too dry. Some persons are of opinion that if land lies under Ray-grass two or three years, it exhausts; and assert, that if one half of a field be laid down with clover, trefoil, &c. and the other half with a mixture of Ray-grass: when it is ploughed for corn, the latter part will be worse to a considerable degree[h]. It would, however, probably be the same with any other grass.

How this species came to be selected originally for cultivation, I cannot say. If it was not accident, it was perhaps because it is common, and the seeds are easily collected. That it should now be the only sort of seed which is to be had in any quantity in the shops, is a disgrace to us, since the best sorts have been so repeatedly pointed out by Mr. Curtis and others, and premiums offered for collecting them, during so many years, by the Society for the Encouragement of Arts, Manufactures and Commerce[i].

2. This is smaller than the preceding. It is distinguished by the tenuity of the culm and spike, which last is cylindrical and awnless; the spikelets are three-flowered[k]. Allione and Villars suppose it to be annual. It is generally looked upon to be no more than a variety of L. perenne. Native of France and Germany. Linnæus remarks that it is very different from Triticum tenellum.

3. Root annual. Stems or culms from two to three feet in height, upright, round, especially near the spike, rough when stroked upwards, having three, four,

[i] Villars and Withering.

or five joints. Leaves flat, pointed, from nine inches to a foot or more in length, and three or four lines in breadth, the upper ſurface rough when ſtroked upwards, the lower ſmooth. Sheaths ſtriated, rough, crowned with a ſhort blunt ligula, ſlightly notched at the edge. Spike from five or ſix inches to a foot in length, rough. Spikelets alternate, in a double row, pale green, half an inch long: the number of flowers in each varying from five to nine. The ſingle valve of the calyx is the length of the ſpikelet, and has not any awn; the terminating flower of each ſpikelet, and frequently the lower ſpikelets, have two calycine valves. The outer valve of the corolla is only half the length of the calyx; it is edged with white, and puts forth below the tip a ſtraight awn, twice its own length. The ſeed is incloſed in the corolla, faſtened to the inner valve, and does not quit it ſpontaneouſly.

There is a variety of this without awns, and with a ſmooth culm, which Withering makes a diſtinct ſpecies, under the name of L. arvenſe, or White Darnel.

Annual Darnel is a native of moſt parts of Europe, Japan, the Cape of Good Hope, &c. Though there can be no doubt of its being a diſtinct ſpecies from the Perennial Darnel, yet we are at a loſs for ſpecific diſtinctions: for that has ſometimes awns to the flowers, and this, not unfrequently, has none. This however is annual, taller and larger in every reſpect, and of a paler hue. Its place of growth is alſo different: for it is a weed among corn, eſpecially wheat and barley, and alſo among flax. It flowers in july and auguſt, later than *L. perenne*.

Virgil joins it with the Wild Oat, as a weed among crops in general——

——" Interque nitentia culta
" Infelix lolium & ſteriles dominantur avenæ[1]."

The epithet *infelix* is probably given it from its deleterious qualities.

Ovid unites it with *Tribulus*, infeſting Wheat——

——" Lolium tribulique fatigant
" Triticeas meſſes & inexpugnabile gramen[2]."

The flour of the ſeeds, mixed with wheat flour, produces diſorders in the human body, as vomiting, purging, and violent cholics, but it has not a ſenſible effect, unleſs taken in conſiderable quantity; or, according to Linnæus, unleſs it be eaten hot. The ſeed, malted with barley, ſoon occaſions drunkenneſs; hence the French name *Ivraie*, and by corruption our Engliſh *Ray*.

In Yorkſhire it is called *Droke*, and in Ireland *Sturdy*.—In Germany *Jakrige Lolch, Germaine Lolch, Somme Lolch, Lulchtreſpe, Betaubende Lolch, Taubkorn, Tollkorn, Taubkraut, Tobbauſor, Taberich, Taberling, Taumel, Taumellolch, Schwindelbaſer, Schwindelkorn, Trunkenweizen, Schlafweizen, Kuhweizen, Rauſch, Rauſchkorn, Dippelbaſor, Sommertreſpe, Traſp, Traſpen, Treſp, Treſpen, Weizentwalch, Twalch, Wendiſche Piank, Radel, Schwanzel, Dert, Treſpendorſt, Treſpdorp, Schafsgraſs, Leitharb, Unkraut, Zizania.* In Denmark, *Hoyre, Fleygregræs, Heire, Swingel, Dude.* In Sweden, *Darrepe.* In Italy, *Loglio, Gioglio, Zizzania.* In Spain, *Joyo, Cizana, Zizana.* In Portugal, *Joyo, Zizania baſtarda.* In Ruſſia, *Kukol.*

In this enlightened age it can ſcarcely be neceſſary to correct an old vulgar error, that wheat degenerates into this graſs. The fact is, that in very wet ſeaſons, and among very bad huſbandmen, Darnel has ſo far prevailed as to ſuffocate the wheat, and to take its place.

Celſus recommends the meal of Lolium to be uſed in poultices, in common with that of wheat, far, barley, and ervum[3].

4. Root annual. Culms ſeveral, from ſix inches to a foot in height, oblique, round, ſmooth, ſomewhat branched. Leaves rolled in a little, acute, naked, much ſhorter than the ſheath, which is ventricoſe and naked. Ligule bluntiſh. Spikelets peduncled, linear, with from four to eight flowers in each. Peduncles ſhort, thickened, rugged. Calycine valve linear, concave, awned. Outer valve of the corolla larger, linear, keeled, awned, rugged: inner ſhorter, linear, flat, awnleſs. Awn twice as long as the floret.

Native of England, on the ſea coaſt, in looſe ſand; flowering in may and june[4].

5. Culms decumbent, branched at the baſe: the flowering ones riſing, a foot high, filiform, narrow, even. Spikes in pairs, terminating, equal, ſeſſile, linear, very narrow, directed one way outwards: flowers alternate, white with ſhaggy hairs. Glume of the calyx ſublateral, linear, blunt, permanent. Corolla ovate, woolly with white ſhagginеſs.

Native of Malabar. Obſerved by Koenig[5].]

PROPAGATION AND CULTURE.

1. *Ray-graſs.*

This Graſs is uſually ſown with Clover, upon ſuch lands as are deſigned to be ploughed again in a few years, and the common method is to ſow it with Spring Corn; but from many repeated trials, I have always found, that by ſowing theſe ſeeds in auguſt, when there has happened a few ſhowers to bring up the Graſs, that the crop has anſwered much better than any which has been ſown in the common way; for the Graſs has often been ſo rank, as to afford a good feed the ſame autumn; and the following ſpring there has been a ton and a half of hay per acre mowed very early in the ſeaſon, and this has been upon cold ſour land; ſo that I am convinced of that being the beſt ſeaſon for ſowing theſe Graſſes, though it will be very difficult to perſuade thoſe perſons to alter their practice, who have been long wedded to old cuſtoms. The quantity of ſeeds which I allow to an acre is about two buſhels, and eight pounds of the common Clover, which, together, will make as good plants upon the ground as can be deſired; but this is not to be practiſed upon lands where the beauty of the verdure is principally regarded, but is fit only for thoſe who have profit in view.

When this graſs is fed, mow off the bents in the beginning of june, otherwiſe they will dry upon the ground, and have the appearance of a ſtubble field all the latter part of ſummer; and they will not only be diſagreeable to the ſight, but troubleſome to the cattle, who will not touch them. By permitting them to ſtand the after-growth of the graſs is greatly retarded, and the beautiful verdure loſt for three or four months, ſo that it is good huſbandry to mow the bents before they grow too dry, and rake them off the ground: if they are then made into hay, it will ſerve for cart-horſes or dry cows in winter.

[Dr. Anderſon affirms, that Ray-graſs requires a deep open looſe deaſish ſoil, tending to dampneſs, to bring it to full perfection. On a ſoil of this ſort he has meaſured ſeveral ſtalks above ſix feet in length.

He obſerves that ſoot, which does not promote the growth of clover, has a ſurpriſing effect upon that of Ray-graſs[6].

Mr. Kent ſays, that Ray-graſs is ſown with clover at the rate of a quarter of a peck to an acre, or by itſelf at the rate of two pecks to an acre, or in the proportion of a gallon to an acre, with eight pounds of clean trefoil; that all cattle are particularly fond of it in the ſpring, but towards midſummer the ſtalks become dry, and cattle then refuſe them; that therefore this graſs ſhould be kept down by being conſtantly fed. When mixed with clover and mowed for hay, it may however be ſpring-fed, and is even the better for it, becauſe it would otherwiſe be ripe before the clover. When ſown with clover its greateſt advantage is experienced in the ſecond and third years, for as the clover declines, this increaſes in proportion. When mixed with trefoil, it is a very good graſs upon light land, deſigned to continue ſeveral years in ſheep-paſture[7].

In Norfolk the ſecond year's lay of Ray-graſs and clover is invariably-paſtured; the ſpring-ſhoot being uſually expended in finiſhing or topping up turnep-fed bullocks; for which purpoſe no other vegetable is perhaps ſuperior to Ray-graſs. Store-cattle follow the bullocks, and keep poſſeſſion of the lays till they

[1] Georg. 1. 153. [2] Metam. l. 5. [3] L. 2. c. 33.
[4] Hudſon. [5] Linn. mant. [6] Eſſays, 2. 300. 309.
[7] Hunt, p. 47.

are broken up for wheat, in july, auguſt, ſeptember or october[1].

Next to Sainfoin, Ray-graſs is in the higheſt eſteem with the Cotſwold farmers. Not only the green herbage, but the hay is there conſidered as ſuperiorly nutritious. Bullocks are finiſhed with ordinary barley and ray-graſs hay; that is, not with the ſtraw of ray-graſs, but with the herbage cut in a ſtate of ſucculency, and properly made[2].

If ſuffered to ſtand too long before it be mown, the hay will of courſe be ordinary. If ſuffered to run up in the ſpring before ſtock be turned upon it, much of it will be left uneaten. If the ſeed ſown be foul, the herbage will be of a bad quality. Under bad management the ſucceeding wheat crop will be unprofitable.

The ſeed ſhould be winnowed, and freed from the ſeeds of weeds, as carefully as the ſeed of wheat or other grain.

If Ray-graſs be intended for paſturage, it ought to be broken as early in ſpring as the land will bear ſtock; which ought to be ſo proportioned, that it never can get above a moderate bite.

If it be ſhut up for hay, it ought to be mown as ſoon as the ſeed-ſtems are fully formed, before the flowers come out.

If it be intended for ſeed, it ought to ſtand until the flowers be fully blown: but it muſt not be expected, in this caſe, that the ſtraw will prove hay.

As a ſpring-ſeed Ray-graſs is preferable to every other graſs; and in autumn it renews its nutritious bite. This property, added to its productiveneſs, and to the facility with which its ſeeds may be collected in quantity, give it a decided preeminence to every other blade-graſs at preſent known.

But this, like other early graſſes, remains in a great meaſure unproductive during the ſummer months. This renders it improper to be ſown alone, for paſturage; and White Clover, the Trefoils, or other ſummer herbage ſhould be cultivated with it.

All perhaps that is wanted in addition to theſe, in order to render the buſineſs of cultivating perennial lays as nearly perfect as common practice may require, is one or more ſummer blade-graſſes of a nutritious quality and productive growth; the ſeeds of which may be eaſily collected ſeparately from the ſeeds of weeds.

Meadow Feſcue (Feſtuca pratenſis) is moſt likely to anſwer this purpoſe; or Meadow Poa (Poa pratenſis) if the ſeeds were eaſily ſeparable.

From a gallon to a peck of clean winnowed ſeed of Ray-graſs is abundantly ſufficient to ſow an acre, when mixed with the Clovers, Trefoil, &c.[3]

In general, where prejudices have ariſen againſt Ray-graſs, it has been becauſe bad ſeed has been ſown, or becauſe the ſoil is improper for it, or that the management has been faulty.

3. Annual Darnel is very injurious to a wheat crop, but may eaſily be avoided, as it is ſown along with the ſeed, from which it may be ſeparated by the ſieve; and not being a root-weed it is unpardonable to ſuffer it to increaſe to any conſiderable degree.

DESCRIPTIONS, &c.

1. This Fern riſes commonly to the height of four or five feet, and is moderately hirſute[1].

Native of South America and Jamaica.

2, 3. Natives of South America.

4. This Fern riſes by a ſimple ſtalk to the height of two or three feet, and then divides into three parts, whereof the middle is ſimple, but each of the lateral diviſions is again parted into three ſimple branches of a proportionate length.

Native of Jamaica, in the mountains of New Liguanee[2].

5. Native of the iſle of Tanna in the South Seas[3].

Mr. Miller has two ſpecies under Lonchitis—

1. L. aſpera, which is *Oſmunda* or *Blechnum Spicant.*

2. L. aſpera major, which is *Polypodium Lonchitis.*

PROPAGATION AND CULTURE.

Theſe Ferns being natives of very hot climates, muſt be planted in pots, and plunged into the bark-pit. They may be increaſed by parting the roots. In ſummer they ſhould have plenty of free air, and be frequently watered.

LONCHITIS. See *Acroſtichum, Adiantum, Aſplenium, Blechnum, Ophioglaſſum, Oſmunda, Polypodium, Pteris.*

LONDON-PRIDE. See *Saxifraga.*]

LONICERA. *So named by Plumier, from Adam Lonicer, phyſician at Frankfort, where he died in* 1588, *aged* 58. —*Methodus herbarum*, 1540. *Kranterbuch*, 1546. *Hiſtoria Naturalis*, 1551, 1555, &c.

Claſſ. 5. 1. Pentandria Monogynia.

Nat. order of *Aggregatæ. Capriſolia.* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* five-parted, ſuperior, ſmall.

COR. one-petalled, tubular; *Tube* oblong, gibbous; *Border* five-parted: *diviſions* revolute, one of which is more deeply ſeparated.

STAM. *Filaments* five, awl-ſhaped, nearly the length of the corolla. *Anthers* oblong.

PIST. *Germ* roundiſh, inferior. *Style* filiform, the length of the corolla. *Stigma* obtuſe-headed.

PER. *Berry* umbilicated, two-celled.

SEEDS roundiſh, compreſſed.

OBS. Capriſolium *has the inferior diviſion of the corolla ſeparated twice as deep. Berries diſtinct.*

Periclymenum *has the diviſions of the corolla cut almoſt equally deep. Berries diſtinct.*

Chamæceraſus *has the lower diviſion of the corolla twice as deeply cut. Two Berries ſeated on the ſame baſe.*

[1] Browne. [2] Ibid. [3] Forſter.

Xyloſteum

Xylosteum *has the divisions of the corolla almost equally cut. Two Berries on the same base.*

Symphoricarpos. *Corolla nearly bell-shaped: Fruit two celled, half-four-celled, seeds solitary.*

L. Alpigena *and* cærulea *are singular in having one germ for two styles, like Mitchella.*

ESSENTIAL CHARACTER.

Cor. one-petalled irregular. *Berry* many-seeded, two-celled, inferior. (In Xylosteum one-celled, in alpigena three-celled. *G.*)

SPECIES.

DESCRIPTIONS, *&c.*

Some authors separate this natural genus of shrubs, keeping the first section or *Periclymena* of Linneus together under the name of *Caprifolium*: the second section or *Chamæcerasa* under the name of *Xylosteum*: and the third with the name of *Diervilla*. The first have twining stems, the leaves of some connate, the flowers sessile in terminating heads or whorls several together. The second have upright stems, and the peduncles two-flowered, axillary and solitary. The third have many-flowered axillary and terminating peduncles[a].]

1. The first sort is commonly called the Italian Honeysuckle; of this there are two or three varieties, the early white Honeysuckle is one; this is the first which flowers, always appearing in may. The branches of this are slender, covered with a light green bark, and garnished with oval leaves of a thin texture, placed by pairs, sitting close to the branches, but those which are situated towards the end of the branches, join at their base, so that the stalk seems as if it came through the leaves. The flowers are produced in whorled bunches at the end of the branches; they are white, and have a very fragrant odour, but are of short duration, so that in about a fortnight they are entirely over; and soon after the leaves appear as if blighted and sickly, making an indifferent appearance the whole summer, which has rendered them less valued than the others. The other variety is the yellow Italian Honeysuckle, which is the next in succession to the white. The shoots of this are much like those of the former, but have a darker bark; the leaves are also of a deeper green; the flowers are of a yellowish red, and appear soon after the white; they are not of much longer duration, and are succeeded by red berries, containing one hard seed inclosed in a soft pulp, which ripens in the autumn.

[This is a very smooth shrub, in its natural state twining round trees with its long, round, opposite branches. Leaves very smooth, conjugate; the lower ones ovate, blunt, connate by a membrane investing the branch, more united under the flowering-stalks, a pair on the flowering-stalks themselves; the uppermost almost orbicular, perfoliate, forming a sort of dish for the flowers; they are all glaucous underneath. Flowers about six in a whorl (or from six to eight, sometimes fewer), slender and delicate, white, reddish white, red, or yellow, extremely fragrant, from an inch and half to almost two inches in length, the lips by no means so long or large as in the Woodbind or German Honeysuckle, but short, and broader in proportion. Stamens and style shorter than the corolla. Berries roundish or subovate, succulent, smooth, red or orange with a black spot at top, containing four or five (from one to six) roundish smooth seeds.

Native of the South of Europe. Cultivated by Gerarde in 1596. It seems then not to have been long known, for Gerarde says, "the double Honi-"suckle groweth now in my garden, and many others "likewise in great plenty, although not long since, "very rare and hard to be found, except in the garden "of some diligent herbarist."

Italian Honeysuckle is named in German *Geißblatt, Durchwachsene welsche oder Italienische Geißblatt, Durchwachs, Je longer je lieber, Jerichorose, Welsche Speckblie, Waldblie, Waldwinde, Zaunling, Gilgenconfori.* In Dutch, *Italiaansche Kamperfolie, Caprifolie, Geitenblad.* In Danish, *Italiensk Gedeblad, Skovlilie.* In Swedish, *Italienst Getblad.* In French, *Chevrefeuille des jardins* or *d'Italie.* In Italian, *Madreselva, Caprifoglio.* In Spanish, *Madreselva.* In Portuguese, *Matrisylva.*

2. Murray called this species *media* because it has the stem and manner of flowering as in the Periclymena, but a short corolla with a gibbose tube, as in the Chamæcerasa[b].

It is a native of North America, and was introduced in 1766, by Peter Collinson Esq. It flowers in june and july[c].]

3. This sort grows naturally in Virginia, and many other parts of North America, but has been long cultivated in the english gardens by the title of Virginia Trumpet Honeysuckle. Of these there are two varieties, if not distinct species, one being much hardier than the other. The old sort, which came from Virginia, has stronger shoots; the leaves are of a brighter green; the bunches of flowers are larger, and deeper coloured than the other which came from Carolina. These plants have the appearance of the common Honeysuckle, but the shoots are weaker than any of those, except the wild sort called Woodbine; they are of a purplish red colour, and smooth. The leaves are of an oblong oval shape inverted, and closely surround the stalk; of a lucid green on their upper side, but pale on their under. The flowers are produced in

[a] Juss.

[b] Linn. syst. 216. n. 6.

[c] Hort. kew.

bunches

bunches at the end of the branches; theſe have long ſlender tubes, which are enlarged at the top, where they are cut into five almoſt equal ſegments. The outſide of the flower is of a bright ſcarlet, and the inſide yellow; they have great appearance of the Honeyſuckle, but are not ſo deeply divided, nor are the ſegments reflexed. They have no odour, but for the beauty of their flowers, and their long continuance, together with their leaves being evergreen, they are preſerved in moſt curious gardens.

[The involucre is very large, and more perfectly connate-perfoliate than even in the firſt ſort. The ſpike of flowers is compoſed of three or four whorls one above another, not ſpread all round, but moſtly turned to one ſide, either quite naked, or having only an imperfect leaf at the baſe. Flower-ſtalk ſingle with one perfoliate leaf, or triple, with a large perfoliate leaf at the baſe of the whole, and a ſmaller one a little below the flowers on each ſide ſtalk. Flowers ſix in each whorl, eighteen to twenty-four in the whole ſpike. Corolla from an inch and half to an inch and three-quarters in length, almoſt ſtraight, very ſlender at bottom, but ſwelling very much at top; lip leſs irregular than in the other Honey-ſuckles, but yet one petal is ſomewhat ſeparated from the reſt, and a little bent back. Stamens the length of the corolla. Piſtil longer.

Ray mentions its being cultivated at Fulham, "in "horto inſtructiſſimo Rev. Epiſcopi Londinenſis "D. Compton." It was however cultivated earlier than this, namely in 1656, by John Tradeſcant Junior. It flowers from may to auguſt[2].]

4. This ſort grows naturally in North America; it has ſtrong branches, covered with a purple bark, which are garniſhed with lucid green leaves embracing the ſtalks, and continuing their verdure all the year. The flowers are produced in whorled bunches at the end of the branches; there are frequently two and ſometimes three of theſe bunches riſing one out of another; they are of a bright red on their outſide, and yellow within, of a ſtrong aromatic flavour. This ſort begins to flower in june, and there is a ſucceſſion of flowers till the froſt puts a ſtop to them, ſo that it is the moſt valuable of all the ſorts.

[Cultivated in 1739, by Mr. Miller.

5. Leaves ſmaller and narrower than in the other ſorts.

Native of Minorca. Introduced about 1772, by Monſ. Richard. It flowers from june to ſeptember[3].]

6. The common wild Engliſh Honeyſuckle or Woodbind trails over buſhes, and twines round the boughs of trees, with its very ſlender hairy (or ſmooth) branches, [which are oppoſite, and commonly ſtained with purple, in part at leaſt or on one ſide. Leaves oppoſite, ovate, ſmooth (or hairy), underneath glaucous, all diſtinct and more ſeparated from the ſtem, though even in theſe there is a ſlight membranaceous ring running round the branch and connecting the two oppoſite leaves. The upper floral leaves are ſeſſile and cordate. Peduncles ſhort, ſingle, or more often triple, covered with glandular hairs, as are alſo the calyx, and tube of the corolla. Flowers in a thick roundiſh whorled ſpike, many together (from ten or twelve to nineteen or twenty;) tube an inch long, curved a little; border two-parted, both parts reflex, the upper one divided into four blunt and nearly equal ſegments, the lower one linear and entire. The tube is wider and ſhorter, the border much longer than in the Italian Honeyſuckle. On account of the border being turned back, the ſtamens ſtand much above the corolla, and the piſtil much above them. The corollas are uſually red on the outſide, and yellowiſh within, but they vary much in colour, between red, purple and yellow, and in the ſhade are very pale. They are very ſweet, eſpecially in the evening. There are very ſmall, whitiſh blunt bodies at the baſe of the ſtyle, which are ſuppoſed to be the nectaries. Berries roundiſh, red, diſtinct, having the remains of the calyx adhering to them, and containing ſeveral ſeeds, of a yellowiſh brown colour, round on one ſide, and flatiſh on the other.

Native of moiſt parts of Europe in woods and hedges, alſo in many parts of the Chineſe empire. With us it flowers from the end of may to july.

The early writers attribute virtues to this ſhrub, which are now quite given up: but the beauty and exquiſite fragrance of the flower ſtill give it a place in our ornamental plantations. In climbing it turns from eaſt to weſt, with moſt of our other Engliſh climbers; and in common with them it bears clipping and pruning well; for in a ſtate of nature, thoſe plants that cannot aſcend without the aſſiſtance of others, are often liable to loſe large branches, they have therefore a proportional vigour of growth to reſtore accidental damages. This ſhrub is ſubject, when placed near buildings, to be diſfigured and injured by Aphides, vulgarly called blights: theſe inſects were formerly ſuppoſed to be brought by the eaſt wind, and conſequently the miſchief was looked upon as inevitable; but obſervation has corrected that error; their hiſtory is well known, but no effectual remedy againſt them is as yet diſcovered. Theſe inſects are not very numerous in ſpring, but as the ſummer advances they increaſe in a ſurpriſing degree: their firſt attacks therefore ſhould be watched, and the branches they firſt appear on cut off and deſtroyed, for when they have once gained ground, they are defended by their numbers. Small plants may be cleared of them by tobacco duſt or Spaniſh ſnuff, but this is not practicable for large trees. The leaves are likewiſe liable to be curled up by a ſmall caterpillar, which produces a beautiful little moth, *Phalæna tortrix*. In the evening ſome ſpecies of Sphinges or Hawk-Moths are frequently obſerved to hover over the bloſſoms, and with their long tongues to extract the honey from the very bottom of the flowers[1]. A conſiderable quantity of nectareous juice may ſometimes be diſcerned in the tube. Inſects that are too large to penetrate into the narrow part of the tube, and have not a long tongue, like the Sphinges, to reach the juice, let it out, by making a puncture towards the bottom, and thus tapping the liquor. The reſources of animals in procuring their food are innumerable.]

β. The late-red Honeyſuckle produces a greater quantity of flowers together than either the Italian or Dutch Honeyſuckle, ſo that it makes a finer appearance than either of them during the time of flowering.

It has not been ſo long an inhabitant of the Engliſh gardens as the Dutch Honeyſuckle, for about the year 1715 it was eſteemed a great curioſity; when it was called the *Flemiſh Honeyſuckle*, and was probably brought over by the Flemiſh floriſts, who at that time came over annually with flowers and plants for ſale[4].

7. The plants of Dutch Honeyſuckle may be trained with ſtems, and formed into heads, which the wild ſort cannot, the branches being too weak and trailing for this purpoſe. The branches of this are ſmooth, of a purpliſh colour, garniſhed with oblong oval leaves three inches long, and an inch and three quarters broad, of a lucid green on their upper ſide, but pale on their under, having very ſhort foot-ſtalks; they are placed by pairs, but are not joined at their baſe. The flowers are produced in bunches at the end of the branches, each flower ariſing out of a ſcaly cover, which cover, after the flowers fade, forms an oval head, whoſe ſcales lie over each other like thoſe of fiſh. The flowers are of a reddiſh colour on their outſide, and yellowiſh within, of a very agreeable odour. This ſort flowers in june, july, and auguſt. There are two varieties of it, one is called the long blowing, and the other the late red Honeyſuckle. ß.

[The ſtems are ſtronger, the leaves larger, the flowers and heads of berries larger, and the corollas redder than in our Woodbind.

δ. This has ſimple leaves, cut like the Oak, and ſmooth. Found firſt near Oxford by Mr. Jenner, and afterwards by Mr. Knowlton, in the way from Hitchin to Wembly[5]. In Sir John Woodhouſe's woods Norfolk, by Mr. Woodward[6].

There is alſo a variety with variegated leaves.

[1] Curtis. [2] Mill. ic. [3] Ray ſyn.
[4] Hort. kew. [5] Ibid [6] Wither. arr.

In Engliſh this ſhrub is Woodbinde, Honeyſuckle, Suckling and Caprifoly.

Shakſpeare ſeems to have diſtinguiſhed the Honeyſuckle from the Woodbine, or Woodbine,

" So doth the Woodbine, the ſweet Honeyſuckle
" Gently entwiſt ——"

Milton appears to have miſtaken it, when he calls it the Eglantine, which is the Sweet Briar.

" Through the Sweet Briar or the Vine,
" Or the twiſted Eglantine."

Shakſpeare clearly diſtinguiſhes the Woodbine from the Eglantine.

" I know a bank whereon the wild Thyme blows,
" Where Ox-lip and the nodding Violet grows,
" Quite-canopied with luſcious Woodbine,
" With ſweet Muſk-roſes and with Eglantine[1]."

The ſame Poet alludes to the uſe of this ramping ſhrub for forming Arbours.

" And bid her ſteal into the pleached bower
" Where Honeyſuckles ripened by the ſun,
" Forbid the ſun to enter"
" ——— Beatrice who e'en now
" Is couched in the Woodbine coverture[2]."

This ſhrub in German is *Specklilie, Geiſslilie, Zaungilgen, Waldgilgen, Baumlilie, Lilie unter den Dornen, Lilienfrucht, Deutſche Geiſsblatt, Deutſche je langer je lieber, Jericheroſen, Georgenroſen, Klein Gilgen Konfort, Aſtranken, Geflochtungene Lautzern, Zaunling, Zaunkreyſeben, Waldrebe, Waldwinde, Waldmerſier, Wilde Ranken, Mennikenkraut.* In Dutch, *Gruwone Kamperfelie, Maanneſeykruid.* In Daniſh, *Gedeblad, Skovilie, Loberoſe, Labelilie.* In Sweduſh, *Matleſtrad.* In French, *La Chevrefeuille des bois.* In Italian, *Caprifoglio, Madreſelva, Vincibosco, Legabosco, Periclimeno.* In Spaniſh, *Madreſelva, Virginia, Periclimeno.* In Portugueze, *Matriſylva do Norte.*

7. Stem round, twining, hirſute, little branched. Branches oppoſite, round, two-leaved, flowering, very hirſute, ſpreading. All the leaves petioled, oppoſite, ovate, ſharpiſh, quite entire, villoſe, pale beneath, an inch long, the upper ones ſmaller. Petioles deflex-ſpreading, hirſute, a little ſhorter than the branches. Flowers at the ends of the branches, terminating in pairs, ſeſſile. Calyx very ſhort. Corolla tubular, irregular, villoſe, red, an inch long. Stamens equal to the corolla. Anthers incumbent. Style the length of the corolla. Stigma headed, undivided.

Native of Japan[3].

8. Height three or four feet. Leaves ſmall, the younger ones hirſute, quite entire, but plaited a little, ſo as to appear ſerrate. Stipules ovate-lanceolate. Bractes two dry ſcales and three tranſverſe broad leaflets. Peduncles axillary, ſlender, an inch long, oppoſite. Calyx broadiſh. Corolla purple on the outſide, white within, or quite white, pubeſcent. Berries black, a little oblong, containing three, five, and ſometimes ten ſeeds[4].

Native of France, Switzerland, Auſtria, Sileſia, Piedmont. It flowers in march, april and may. Cultivated in 1683[5].

The Japoneſe plant, which Thunberg in Flora Japonica took for this, is ſince made a new ſpecies by him, under the name of L. flexuoſa[6].]

9. This grows about the ſame height with the preceding and fourteenth ſort, and it bears a great reſemblance to them in the branches; but the leaves are heart-ſhaped, and the berries are red, growing ſometimes ſingle, at others double, and frequently there are three joined together; they are about the ſame ſize with the preceding.

The leaves are ſmooth, on ſhort petioles. Involucre lanceolate: involucels obovate. Corolla pale fleſh-colour, the upper lip three-parted, the middle ſegment biſid, the lower ſimple[7].

Profeſſor Pallas deſcribes it more particularly thus.—It is a tree frequently a fathom in height, but commonly leſs, riſing with ſeveral trunks, often thicker than the wriſt, ſpreading, branched very much from the bottom; covered with a brownish-gray, ſmoothiſh bark, cloven longitudinally. Branches knobbed, with a whitiſh-gray ſmooth bark, ſhooting off the epidermis. Shoots oppoſite, ſmooth, bearing both leaves and flowers. Leaves oppoſite, tender, bright glaucous green petioled, cordate-lanceolate, very ſmooth, except the edge which is ciliated with very tender hairs. Stipules none. Above the peduncles a wart-like gland, which on the woody branches is permanent, and puts forth buds. Peduncles from the upper axils of the leaves ſolitary, at a little diſtance from the petioles, oppoſite, making half a right angle with the ſhoot. Involucre of each pair of flowers ſix-leaved, the two outer leaflets almoſt the ſame length with the tube of the corolla and linear, the other four lanceolate, blunt and ſub-croſe at top, reddiſh. Germs inferior, perfectly ſeſſile within the involucre. Calyx above the germ minute, five-toothed, the teeth blunt and croſe, reddiſh. Corollas before they open parallel, club-ſhaped, of a deep roſe colour, when open fleſh-coloured, diverging; tube gibbous at the baſe from the nectary; border ſpreading, irregularly five-cleft, ſegments concave, more coloured on the outſide, the three upper ones leſs deeply cut, broadiſh, upright; the lower ones narrower, cut to the tube, divaricating downwards. When the flower is imperfectly expanded, the three upper ſegments frequently, the two lower ſometimes, are glued together. Stamens from the jaws of the corolla, ſhorter than the border; filaments pubeſcent at the baſe; anthers erect, oblong, four-grooved, yellow. Style a little ſhorter than the filaments, white, hairy, deciduous with the flower. Stigma fungus-ſhaped, green, bent back like a tongue, having commonly a ſimilar lobule but ſmaller at the baſe. Berries diſtinct, ſcarlet, ſucculent, one of them often abortive. Seeds oblong, flat, yellowiſh.

In ſhady groves it varies with a white flower. In autumn the leaves put off their fringes and become quite ſmooth.

Native of Ruſſia, but not beyond 55° of latitude. In the more ſouthern parts it flowers in may, in the eaſtern and in gardens at Peterſburgh in june.] With us it flowers in april, and the fruit is ripe in july. [It is frequented by the Meloe veſicatoria, and the inſect is collected from this ſhrub for the Apothecaries. The berries are eaten by the common people, though they are naſeouſly bitter, and are apt to purge. The flowers have hardly any ſmell; the leaves are bitterſh. The wood is very hard and ſolid, of a yellowiſh gray colour, beautifully veined, and uſed to make walking ſticks and the handles of tools[8].

Cultivated in 1752, by Mr. Miller[9], to whom the ſeeds were ſent from the Imperial garden at Peterſburgh, to which they were conveyed from Tartary.

10. Fly Honeyſuckle riſes with a ſtrong woody ſtalk ſix or eight feet high, covered with a whitiſh bark, dividing into many branches. Leaves ovate, oppoſite, entire and covered with a ſhort hairy down. The flowers come out on each ſide of the branches oppoſite, on ſlender peduncles, each ſuſtaining two white flowers ſtanding erect. The three lower legments of the corolla are narrow and reflex, the other two are broader and upright.

[Leaves oppoſite, three pairs on each branch, rather ſoft, and like cloth to the touch. Peduncles oppoſite, axillary. Corolla yellow, upper lip four-cleft, lower linear, entire. Filaments woolly[10]. The corolla with us is uſually a dirty white, but it is often yellowiſh, or doll purple on the outſide, where it is alſo pubeſcent.

Berry inferior, ſpherical, crowned with the rudiment of the calyx, (red or black, full of a dark purple watery pulp), ſubtranſparent, one-celled. Seeds ſix to twelve, placed without order or in a ring, ſubcartilaginous, hard, compreſſed a little or angular, red[11]. Scopoli and Adanſon ſay, that the berries have three cells, with two ſeeds in each.] Mr. Miller ſays that

they

they are red and clammy, joined at their base, and ripe in the beginning of september.

[Linnæus says, that this shrub makes excellent hedges in a dry soil; that the clear parts between the joints of the shoots are used in Sweden for tobacco-pipes, and that the wood, being extremely hard, makes teeth for rakes, &c. Gmelin informs us that the Russians prepare an empyreumatic oil per descensum from the wood, which they recommend for cold tumours and chronical pains. Animals seldom touch the leaves. Birds eat the berries only in hard weather. They are reputed purgative and emetic.

Native of the North of Europe, and even of the South of France, Italy, and Hungary. Common in Russia, especially the more northern parts, and in Siberia as far as the river Jenisea. Also in Kamtschatka, with black berries: and in Cochinchina, according to Loureiro. According to Withering, it is a native of England. It appears in all our plantations of shrubs, and was cultivated, according to Sutherland, in 1683[1]. It flowers in may.]

11. This seldom rises more than three or four feet high, dividing into several spreading irregular branches. The flowers come out from the side of these on slender peduncles, each sustaining two white flowers, which are cut into five segments almost to the bottom.

[It differs from the preceding in having regular corollas, divaricated branches, and smooth leaves[2].

Native of the Pyrenean mountains and Siberia.—Cultivated in 1739, by Mr. Miller[3], who received a plant of it from the Duke D'Ayen's garden at St. Germain's. He says that it grows also naturally in Canada; and that it flowers in april.

12. This has a short thick woody stem, which divides into many strong woody branches growing erect. Leaves petioled, entire, dark green above but pale underneath. Flowers upon very long slender peduncles, which come out opposite on each side of the branches, at the base of the leaves; they are red on the outside, but pale within, shaped like those of the Fly Honeysuckle, but a little larger, and standing erect. They appear at the end of april, and are commonly succeeded by two ovate red berries, joined at the base, and having two punctures. They ripen at the beginning of august. Sometimes there is but one berry, which is frequently as large as a Kentish Cherry.

[The berry is thus described by Gærtner. It is on a long peduncle, ovate, red, composed of two berries, each of which is most manifestly three-celled: cells clothed with their proper membrane, and separate from the seeds all round, but sometimes obliterated when ripe. Seeds in each cell regularly two, and therefore twelve in the whole; but no more than two or three of them come to maturity, and these are large, subovate, thick, very smooth, pale straw-colour, on one side convex or irregularly gibbous, flat or somewhat concave on the other, shining. Because the berry is three-celled, and the seeds loose and shining, Adanson has separated this from the other species, under the name of *Ibra*, and Gærtner seems inclined to follow him. At this rate, we might form a genus of almost every species.

Linnæus remarks, that the leaves are smooth; the corollas without any spur, and irregular; the two upper segments of the calyx scarcely distinct.—Scopoli, that the leaves are shining underneath; the peduncles striated, a finger's length, with two bractes on them; the filaments hairy at the base, and the anthers of the same colour with the corolla, which according to him is red, but according to Linnæus, yellow. Krocker says it is blood-red.

Native of the South of Europe. Cultivated by Gerarde in 1596[4].

In his Herbal, having figured Lonicera nigra, Xylosteum, caerulea, and tatarica, he says that he has a plant of the *first* kind in his garden, but that he had not as yet seen the rest. Johnson names this *Cherry Honeysuckle*.

13. Height about five feet; trunk covered with a whitish bark; branches spreading, red or hoary-testaceous; branches long, slender, wand-like. Leaves opposite, approximating, on very short petioles, ovate-lanceolate, an inch broad, quite entire except that they are sometimes a little sinuated, nerved, smooth as is the whole shrub. Peduncles axillary, solitary, half an inch long, and therefore much shorter than in *L. nigra*, which this sort most resembles, upright. Germ crowned with two calyxes distinct, having the tube very short, and the teeth longer. Stipules two, setaceous-linear, scarce apparently serrulate, under the germ, and nearly equal to it. Corolla irregular, red; tube funnel-form; lower segment bent down, simple, narrower, oblong; upper broad, four-lobed. Stamens a little longer than the corolla; anthers oblong, from erect incumbent, pale. Style curved in, simple. Fruiting peduncle erect. Berry twin-globular, dark blue, with two lanceolate bractes under it, and the rudiments of the calyxes at top. Seeds in both parts of the berry ten, greenish white, rounded, compressed. The wood is hard, weighty, like ivory, beautifully veined with green; much esteemed for walking sticks, which are sent to Peterburgh.

Native of Caucasus. Called by the Russians *Tegusum* and by the Tartars *Tekut-tuun*, which signifies nine skins; this shrub every year casting its epidermis, which adheres copiously to the twigs.]

14. This seldom rises more than four or five feet high. The branches are slender, covered with a smooth purplish bark. The joints are distant, where leaves come out opposite, and sometimes there are two on each side. The peduncles are very short, each sustaining two white flowers, succeeded by blue berries single and distinct. The flowers appear in may (march or april), and the berries ripen in august.

[Height from three to five feet. Very much and irregularly branched from the bottom. Branches opposite, in the full-grown shrub smooth, fulvous, scariose all over with the rags and tatters of the epidermis. Wood very hard, beautifully veined with gray and pale yellow. At all the branchlets are opposite wooden stipules, transversely subconnate, seeming to arise from the permanent petioles of the fallen leaves. On the shoots of the year, from the axils of the leaves sharp buds spring, which the next year form new branchlets. The younger branchlets, especially when luxuriant, are ferruginous, and extremely hirsute with clustered hoary hairs. Leaves opposite, on short pubescent petioles, ovate or ovate-oblong, pubescent underneath, but becoming smooth with age. Peduncles axillary, solitary, nodding, smooth, two-flowered, and sometimes though seldom three-flowered. Germ subglobular, smooth, crowned with the calyxes which are very shortly toothletted, and accompanied by two setaceous hairy stipules, twice as long as the germ. Corollas pale (Linnæus says, yellow), large, funnel-form, with a hairy tube, gibbous at the base on the outside with the nectary, border smooth, with ovate segments. When there is a third flower it has a slender tube and no nectary. Stamens shorter than the border of the corolla, with oblong erect pale anthers. Style simple, a little longer than the segments of the corolla, with a simple capitate stigma. Berries at first subglobular, when ripe oblong, large, dark blue, with a bitterish purple juice, and six or eight small, oblong, acute, yellow seeds. The purple juice stains paper of a strong colour, and might perhaps be useful in dyeing[5].

Native of Switzerland, Austria, Siberia as far as Kamtschatka, and in the islands adjacent to America. —Cultivated here in 1724[6].

15. This is smaller than *L. Xylosteum*, upright, with slender branches, straight, opposite, spreading, with a whitish-gray outer bark. Leaves fewer, opposite, petioled, hoary underneath. Peduncles terminating, between the last pair of leaves, the length of the petioles, bifid, sustaining on each two, four or five sessile flowers. Calyx none, but a rim crowning an inferior, cylindric striated germ. Corolla yellowish white, equal, small, bell-shaped, five-toothed. Sta-

[1] Hort. ken. from hort. edinb. 77. n. 1. [2] Linn. spec. [3] Hort. ken. [4] Ibid. [5] Pallas. [6] Ibid. [7] Horr. ken. from Farber's catalogue, in Mill. dict.

mens

mens the length of the corolla, with large twin anthers. Germ within the flower, prominent with a very short umbilicus, and a truncated stigma. Berry globular, large, ovate-depressed, convex on the outside, containing five, six or seven seeds. Not only in the desert of the Mongols in the Russian Empire, but in Dauria[a].]

16. Height about four feet, sending out many slender branches. Leaves ovate, hairy, opposite, on very short petioles. The flowers are produced in whorls round the stalk; they are of an herbaceous colour, and appear in august. The fruit, which is hollow, and shaped like a potage pot, ripens in the winter. [The corollas are regular and bell-shaped. The fruit fleshy, globular, the form and size of the flowers of Arbutus, four-celled, containing cartilaginous roundish seeds. The flowers and fruits are axillary, and being in close clusters, Dillenius gave this shrub the name of *Symphoricarpos*. The leaves grow in ten pairs or more on a stalk, like pinnate leaves; they are somewhat glaucous underneath, being covered with a fine down. The fructification is not unlike that of Cuscuta in appearance, but not in structure[b].

Native of Virginia and Carolina. Cultivated in 1730. It flowers in august and september[b].

17. Branches round, smooth, compressed at top, somewhat villose, dilated a little under the leaves, and knobbed where they have fallen. Leaves opposite, on short petioles, subcoriaceous, three inches long, smooth, except that they have a few hairs on the midrib, nerved, veinless, abundance of small hairs in the axils of the leaves. Heads of flowers on short pedunclés at the ends of the branchlets, fix together, sessile, supported on each side by a petioled leaf, and surrounded by a very short, ovate, acute, villose, many-leaved involucre. Calyx rough-haired; segments linear-lanceolate, shorter than the corolla: which is villose on the outside, ash-coloured, the form of Comfrey. Capsule two-celled, crowned with the permanent calyx scarcely of this genus. Found by Sparrman at the Cape of Good Hope, where the Dutch call it *Buffelbourn*[c].

18. This is a low shrub, seldom rising more than three feet high. The stalks are slender and woody, and have a reddish-coloured bark. Leaves oblong, pointed, slightly serrate, opposite. Flowers small, pale yellow, two or three on each division of the raceme. Berries oval, black, four-celled, with one hard seed in each cell. In England they are rarely formed, and never come to maturity.

The roots creep far under ground, and send out many stems: many of these which come up in the spring produce flowers the same year, so that there is generally a succession of them from may to september; the shoots of the former year flowering early, the side branches soon following, and then the young shoots. It is a native of North America, and was first brought to Europe from Acadie by Mons. Dierville a French surgeon, whence Tournefort gave it the name of *Dierzilla*[a].—Mr. Miller cultivated it in 1739[d].

19. Native of Peru.

PROPAGATION AND CULTURE.

All the sorts of Honeysuckle are propagated either by layers or cuttings. When by layers, the young shoots only should be chosen. They should be layed in the autumn, and by the following autumn they will have taken root, when they should be cut off from the plants, and either planted where they are to remain, or into a nursery to be trained up, either for standards, which must be done by fixing down stakes to the stem of each plant, to which their principal stalk should be fastened, and all the other cut off; the principal stalk must be trained to the intended height of the stem, then it should be shortened to force out lateral branches, and these should be again stopped to prevent their growing too long; by the constant repeating this as the shoots are produced, they may be formed into a sort of standard; but if any regard is had to their flowering, they cannot be formed into regular heads, for by constantly shortening their branches, the flower-buds will be cut off, so that few flowers can be expected; and as it is an unnatural form for these trees, so there should be but few of them reduced to it, for when they are planted near other bushes, in whose branches the shoots of the Honeysuckles may run and mix, they will flower much better, and have a finer appearance than when they are more regularly trained; therefore, when the plants are in the nursery, if two or three of the principal shoots are trained up to the stakes, and the others are entirely cut off, they will be fit to transplant the following autumn, to the places where they are to remain; for though the roots may be transplanted of a greater age, yet they do not thrive so well as when they are removed while they are young. When these plants are propagated by cuttings, they should be planted in september, as soon as the ground is moistened by rain. The cuttings should have four joints, three of which should be buried in the ground, and the fourth above the surface, from which the shoots should be produced. These may be planted in rows, at about a foot distance row from row, and four inches asunder in the rows, treading the earth close to them; and as the Evergreen and late red Honeysuckles are a little more tender than the other sorts, if the ground between the rows where these are planted, is covered with tanner's bark, or other mulch to keep out the frost in winter, and the drying winds of the spring, it will be of great advantage to the cuttings; and if the cuttings of these sorts have a small piece of the two years wood at their bottom, there will be no hazard of their taking root. The plants which are raised from cuttings, are preferable to those which are propagated by layers, as they have generally better roots.

These plants will grow in almost any soil or situation, except the fourth, which will not thrive where it is too much exposed to the cold in winter: it thrives best in a soft sandy loam, and will retain its leaves in greater verdure in such ground than if planted in a dry gravelly soil, where in warm dry seasons the leaves often shrink, and hang in a very disagreeable manner; nor will those sorts which naturally flower late in the autumn, continue so long in beauty on a dry ground, unless the season should prove moist and cold, as those in a gentle loam, not too stiff or wet.

There are few sorts of shrubs which deserve cultivation better than most of these, for their flowers are very beautiful, and perfume the air to a great distance with their odour, especially in the mornings and evenings, and in cloudy weather, when the sun does not exhale their odour, and raise it too high to be perceptible; so that in all retired walks, there cannot be too many of these intermixed with the other shrubs. I have seen these plants intermixed in hedges planted either with Alder or Laurel, where the branches have been artfully trained between those of the hedge; from which the flowers have appeared dispersed from the bottom of the hedge to the top, and being intermixed with the strong green leaves of the plants which principally compose the hedge, they have made a fine appearance; but the best sorts for this purpose, are the Evergreen and long-blowing Honeysuckles, because their flowers continue in succession much longer than the others.

These shrubs may also be propagated by seeds, but unless they are sown in the autumn soon after they are ripe, the plants will not come up the first year.

3. The Trumpet-Honeysuckle is usually planted against walls or pales, to which their branches are trained; for they are too weak and rambling to be reduced to heads, and are liable to be killed in severe winters. This sort therefore should have a warm aspect, where it will begin to flower at the end of june, and there will be a succession of flowers till the autumn. [It may, however, be trained like the other Honeysuckles, and will flower among other shrubs, in the south border of a plantation in a warm soil, till a winter more than ordinarily severe injures or kills it.] It is propagated by laying down the young branches, which will easily take root, and may be afterwards treated like the common Honeysuckles.

[Mr.

[a] Pallas. [b] Dillenius. [c] Hort. kew.
[d] Vahl and Linn. suppl. [e] Mill. fig.
[f] Hort. kew.

[Mr. Miller treats of the above, under the old name Periclymenum: and of the upright Honeysuckles under Lonicera.]

These not being so beautiful, a few only should be admitted in plantations. They are all very hardy, and will thrive in a cold situation better than in a warm one; they love a moist soil, and will produce a greater quantity of fruit in that than in a dry one.

They may be increased either by seeds or cuttings. The seeds commonly lie in the ground a year before they vegetate. If they are sown in autumn, however, many will grow the following spring. The cuttings should be planted in autumn in a shady border, where they will put out roots the following spring, and in the autumn they may be removed into a nursery, to grow two years to get strength, after which transplant them where they are to remain.

18. L. Diervilla, [which Mr. Miller, following Tournefort, separates under the name of Diervilla] multiplies greatly by its spreading roots, sending up abundance of suckers. It loves a moist soil and shady situation, where cold will never injure it.

LOPPING. It is very observable, that most old trees are hollow within, which does not proceed from the nature of the trees, but is the fault of those who have the management of them, who suffer the tops to grow large before they lop them, as the Ash, Elm, Hornbeam, &c. and persuade themselves that they may have the more great wood: but, in the mean time, do not consider that the cutting off great tops, or branches, endangers the life of a tree, or, at best, wounds it so, that many trees yearly decay more in their bodies, than the yearly tops come to; and at the same time that they furnish themselves with more great wood, they do it at the loss of the owner. And, indeed, though the Hornbeam and Elm will bear great tops when the body is little more than a shell, yet the Ash, if it comes to take wet at the head, very rarely bears more top after the body of the tree decays; therefore, if once these trees decay much in the middle, they will be worth little but for the fire, so that if you find a timber tree decay, it should be cut down in time, that the timber be not lost.

The Lopping of young trees, that is, at ten or twelve years old at most, will preserve them much longer, and will occasion the shoots to grow more into wood in one year, than they do in old tops at two or three. But when great boughs are ill taken off, it often spoils many a tree, for which reason they should always be spared, unless there is an absolute necessity. When they must be cut off, it should be close and smooth, and not parallel to the horizon, and cover the wound with loam and horse-dung mixed, to prevent the wet from entering the body of the tree.

When trees are at their full growth, there are several signs of their decay, as, the withering or dying of many of their top branches; or if the wet enters at any knot, or they are any-wise hollow, or discoloured, if they make but poor shoots, or if woodpeckers make any holes in them.

This Lopping of trees is only to be understood for pollard trees, because nothing is more injurious to the growth of timber trees, than that of Lopping or cutting off great branches from them; whoever will be at the trouble of trying the experiment upon two trees of equal age and size, growing near each other, to lop or cut off the side branches from one of them, and suffer all the branches to grow upon the other, will, in a few years, find the latter to exceed the other in growth every way, and this will not decay near so soon.

All sorts of resinous trees, or such as abound with a milky juice, should be lopped very sparingly, for they are subject to decay when often cut. The best season for Lopping these trees, is soon after Bartholomew tide, at which time they seldom bleed much, and the wound is commonly healed over before the cold weather comes on.

LORANTHUS. (*From λορος a strap, and ανθος, a flower; the corolla being cut into straps.*)

Lin. gen. n. 443. *Reich. n.* 478. *Siberb. n.* 600. *Vaill. act. par.* 1720. *Jacqu. amer.* 97.

Lonicera. *Plum.* 37. *Gertn. t.* 27.

Class. 6. 1. Hexandria Monogynia.

Nat. order of *Aggregatæ*. *Caprifolia*. Juss.

GENERIC CHARACTER.

Cal. *Perianth of the fruit* inferior: margin entire, concave—*of the flower* superior, or the margin entire, concave.

Cor. *Petals* six, oblong, revolute, equal.

Stam. *Filaments* six, awl-shaped, fattened to the bases of the petals, the length of the corolla. *Anthers* oblong.

Pist. *Germ* oblong, between the two calyxes, or inferior. *Style* simple, the length of the stamens. *Stigma* blunt.

Peric. *Berry* oblong, one-celled.

Seed oblong.

Obs. L. europæus *has dioecous flowers*; *and* L. pentandrus *has half-five-cleft five-stamened flowers*.

ESSENTIAL CHARACTER.

Germ inferior. *Cal.* none. *Cor.* six-cleft, revolute. *Stami.* at the tips of the petals. *Berry* one-seeded.

SPECIES.

Viscum latioribus & subrotundis foliis, flore purpureo. *Sloan. jam.* 2. 92. *t.* 200. *f.* 2.
Racemes simple, flowers irregular.

9. Loranthus loniceroides.
Lin. spec. 473. *fyst.* 343. *Reich.* 2. 109. *spec. ed.* 1. 175. *fl. zeyl. n.* 83. (Lonicera). *Pluk. phyt. t.* 213. *f.* 5. (Periclymenum). *Rheed. mal.* 1. 55. *t.* 29. (Iru Canni).
Flowers aggregate-capitate.

10. Loranthus Stelis.
Lin. spec. 473. *Reich.* 2. 109. *Loefl. it.* 87. *Forst. flor. austral. n.* 157.
Racemes trichotomous, peduncles three-cornered, flowers equal.

11. Loranthus parvifolius.
Swartz. prodr. 58.
Pedunculis axillaris, trifidis, pedicels one-flowered, leaves ovate, entire.
12. Loranthus pauciflorus.
Swartz. prodr. 58.
Pedunculis trichotomis, shorter than the leaves, leaves obovate.
13. Loranthus pentandrus.
Lin. fyst. 344. *Reich.* 2. 109. *mant.* 63.
Racemes simple, flowers five-cleft, leaves alternate, petioled.
14. Loranthus falcatus.
Lin. fyst. 344. *fuppl.* 211.
Racemes few-flowered, axillary, leaves linear, blunt, laterally fickled, glaucous.
15. Loranthus fpicatus.
Lin. fyst. 344. *Reich.* 2. 109. *mant.* 63. *Jacqu. amer.* 97. *t.* 68. *pict.* 50. *t.* 99.
Spikes quadrangular.
16. Loranthus cochinenfis.
Lour. cochinch. 195.
Peduncles many-flowered heaped, leaves acute.
17. Loranthus pedunculatus.
Jacqu. amer.
Racemes fimple folitary, flowers in threes, peduncled.
18. Loranthus feffilis.
Jacqu. amer.
Racemes fimple folitary, flowers in threes, feffile.

DESCRIPTIONS, *&c.*

Thefe are moftly parafitical fhrubs: the leaves thickifh, often oppofite, but fometimes alternate. Flowers axillary, fometimes but feldom terminating, corymbed or fpiked, or on one-flowered pedicels; fome five-petalled, five-ftamened; fome one-petalled, the petals being united at the bafe: in L. europæa they are dioecious. According to Jacquin, three alternate anthers, in L. unifiorus, are effete; in L. pedunculatus they have two appendicles at the top, and are often barren. Juffieu fuggefts, that the genus might perhaps be divided, by reftoring the name of Lonicera to fuch fpecies as have fix ftamens, and giving that of Loranthus to thofe which have five [a]. Some of thefe plants were named *Scurrula* by Browne, from *Scurra* a Parafite; on account of their drawing nourifhment from other trees.

1. Leaves oppofite, quite entire. There is a fingle flower on each fide by the leaves, making four at each joint, and fo along the whole ftem. Native of New Zealand [b].

2. Leaves oppofite, petioled, quite entire, fmooth, a little broader on one fide than on the other. Flowers axillary, three to fix, each on its proper pedicel. Germs attenuated below. Native of China [c], and the Philippine iflands.

3. Leaves fuboval, blunt, with a fmall point, entire, very fmooth, coriaceous, petioled, oppofite, frequently irregular. Racemes axillary and terminating, folitary; pedicels one-flowered. Flowers fmall, inodorous. Calyx of the fruit trifid; fegments ovate, concave, acute, upright. Petals purple, blunt, fpreading very much, of the fame length with the germ. Filaments half the length of the petals, three of them fomewhat longer, commonly without anthers, but inftead of them a colourlefs body like an anther, but without pollen. Berry cylindrical, flatted on both fides, with a dark rind, and a gluminous milky pulp. Native of St. Domingo, in woods, flowering in november and december [d].

4. Native of the Cape of Good Hope.

5. This has the ftature of Vifcum album. Calyx obfoletely fix-toothed. Petals and ftamens fix. Germ inferior. Flowers male and female on feparate plants. Berry yellow, containing one feed. Native of Auftria, parafitical on oaks [e]: alfo of Siberia [f].

6. Branches fubdivided, leafy, fmooth, pale green, brittle. Leaves petioled, oppofite, entire, fubcoriaceous, nerved, pale. Petioles fhort, compreffed, fmooth. Racemes fubdivided, terminating, with three-cornered branchlets; the laft pedicels trifid, one-flowered. Flowers red. Calyx double: lower undivided, pitcher-fhaped, fmall: upper, margin of the germ, entire. Petals fix, very long, contiguous below, fpreading above, revolute; before they are unfolded forming a ftiglitly incurved corolla. Filaments fattened to the petals above the middle, filiform, purple. Anthers oblong, vertical, yellow. Germ ovate. Style filiform, the length of the corolla. Stigma blunt, pubefcent. Berry ovate, one-feeded [g].

It ramps over the higheft trees in Jamaica, Martinico, &c. efpecially the Coccoloba grandifolia, with the root adhering firmly to the bark like Miffelco. If a large bough, on which it grows, be cut off, the next day it withers and periflhes [h].

7. Native of Hifpaniola.

8. Branches divaricating, fubdivided, looſe, round, rugged, brittle. Leaves large, on fhort petioles, oppofite, ovate-rounded, margined, fpreading, nerved above, fmooth, fucculent, pale green. Racemes axillary, folitary, erect, fhorter than the leaves, roundifh, on very fhort thick peduncles; flowers feffile, minute, dark purple. Calyx fuperior, minute, undivided. Petals almoft connate at the bafe; three a little fhorter, upright, acute. Filaments fhorter than the petals, and placed on the middle of them. Anthers three, ovate, yellow, fertile; three barren, hollowed on the fides for the fertile ones. Germ inferior, roundifh, covered with the calyx, and margined. Style the length of the petals. Stigma fimple, blunt. Berry roundifh, viſcid, one-feeded [i].

Native of South America and the Weſt-Indian iflands. Carthagena, Jamaica, &c. on trees; flowering in april and may.

9. This has long flexuoſe branches. Leaves oppofite, ovate-lanceolate, thick, petioled, quite entire, fmooth, veined, bluntifh. The top of the peduncle bears an involucre with five lanceolate leaves, within which are three, four or five feffile flowers, tubular, with a five-cleft mouth, and lanceolate fegments. Stamens five, with the filaments inferted into the fegments of the petal. Style capitate. Berry under the calyx [k]. Native of the Eaft Indies.

Gertner has a fpecies of this genus, which he names *Lonicera zeylanica*. He fays, that it is not Loranthus loniceroides, which has the flowers feffile in a peduncled umbel; and that it does not agree with Loranthus americanus, which has fpherical berries difpofed in a cyme; whereas in this the berries are oval in a much lengthened raceme. The corolla is fix-cleft, and it has fix ftamens. The embryo is inverted, and has only one cotyledon, which is almoft as long as the albumen, fubfufiform, folid, and without any veftige of a diviſion. In the cavity of the albumen of old berries there is often a white pellucid cryſtallized reſin like Camphor [l].

10. Native of South America, and the Society iſles [m].

11, 12. Natives of Jamaica [n].

13. Branches dilated at the leaves, which are of the ſame form with thoſe of the Bay, with fcarcely any nerves. Racemes axillary, folitary or in pairs, a little longer than the petioles. Corollas half-five-cleft. Stamens five, from the middle of the fegments of the corolla; filaments fhorter than the anthers, which are erect, and the length of the corolla. Native of the Eaft-Indies [o].

14. Leaves fickle-fhaped, with the edge verging downwards, quite entire, veinleſs, hoary. Flowers fickle-fhaped, orange. Found by Koenig, growing on trees about Madras [p].

15. This branching fhrubby plant grows on other fhrubs. The root divides in two, furrounding the branch to which it faftens itſelf, and then uniting again; it there puts out fibres on every ſide, and runs along the branch frequently to a great length. Branches woody, diffuſed, brittle. Leaves quite entire, blunt, ſmooth, coriaceous, fat to the touch, petioled, oppo-

fite,

fite, with afcending veins or nerves almoft all fpringing from the bafe; their figure varies, being ovate, oval, obovate or roundifh. Spikes oblong, thick, fquare, four-grooved, axillary, folitary, not exceeding the leaves. Flowers fmall, inodorous, red, very many, deeply feffile in four longitudinal rows. In thefe the calyx of the fruit is only a little fcale, with an irregular mouth. Petals half erect at the bafe, refemble a one-petalled corolla, at top they fpread very much equally, and are double the length of the ftamens. Germ fmall, immerfed in the fpike. Berry ovate-oblong, green with a red tip, and containing a milky glutinous juice. Native of Carthagena in New Spain, in woods; flowering in april and may *.

Swartz doubts whether the L. fpicatus of Jacquin juft defcribed be different from L. occidentalis of Linnæus (n. 8.); the leaves, manner of flowering and flowers being fcarcely different, and Sloane's figure not unlike Jacquin's *.

Juffieu fufpects that the *Glutago* of Commerfon may be the fame with L. fpicatus of Linnæus. He defcribes it as a parafitical fhrub; the calyx fcarcely five-toothed, with two appendicles at the bafe; corolla firft tubular, then cloven at the fide, and expanded into a flat ftrap (thereforе like Scævola) five-cleft at top, five-ftamened, with the antheriferous fegments revolute; berry glutinous, containing one feed *.

16. Stem woody, twifted, three, very much branched. Leaves ovate-lanceolate, quite entire, oppofite, clofe, fmooth, curved inwards, reflex. Flowers herbaceous, axillary. Calyx inferior, three-leaved, very fmall. Corolla fuperior, one-petalled; tube wide, hexagonal; border deeply fix-parted, fegments lanceolate-linear, opening elaftically, revolute. Stamens fix. Style longer than the ftamens; ftigma fpheroidal. Berry between the calyx and corolla, yellowifh red, crowned, containing one, ovate, fix-grooved feed.

Native of Cochinchina, on the branches of trees in gardens *.

17. Root as in fpicatus. Branches fhining, long, reclined. Leaves cordate-ovate, quite entire, with a fhort point, fhining, coriaceous, petioled, oppofite, two inches long, with veins from the midrib. Racemes axillary, fhorter than the leaves, containing about twenty-one flowers; peduncle compreffed, broad; partial peduncles three-flowered; the proper ones one-flowered. Flowers inodorous, fmall; calyx of the fruit ovate, concave, entire; petals white. Filaments half the length of the petals, three of them in alternate order having two roundifh appendicles. It happens frequently that there are no anthers, but cufped upright bodies in their place; and hence the flowers in this fpecies are very frequently abortive.

Native of Carthagena, in woods, efpecially in falt marfhes.

18. This has the habit of the preceding, but the branches as in L. fpicatus. Leaves ovate, an inch and half long. Flowers have no proper peduncles, but are placed on the thickened top of the partial peduncle. All the filaments are always antheriferous. Berries of a dufky greenifh red colour. Native of Carthagena, in woods *.

DESCRIPTIONS, *&c.*

Theſe are moſtly herbaceous plants, more perennial than annual: ſome few woody at bottom, and one arboreous. Leaves ternate, petioled with ſeſſile leaflets, and two large ſtipules, of the ſame form with the leaflets, but diſtinct from the petiole; hence the leaves have been called quinate, though they are properly ſo only in one ſpecies, beſides Dorycnium. Peduncles ſolitary, axillary and terminating; in moſt having one leaf at top, and either few-flowered, or many-flowered in a head or umbel. Corollas moſtly yellow, changing readily to blue. Dorycnium recedes in ſome degree from the other ſpecies: the peduncles are leafleſs and many-flowered, and the leaves digitately five-leaved. Lamark has referred it to Aſpalathus [a].

The name Λωτος or *Lotus* is given by the ancients both to an herb and a tree, each different from the plants contained in this genus. The herb is a ſpecies of Nymphæa [b], and is joined by Homer with Smallage, as forming the green food of Achilles's horſes.

Λωτον τερπομενοι ελεοσελινον τε νεμοντο [c].

The Lotus being ſo abundant in the Nile, and a plant ſo famous in Egypt, may ſuggeſt a preſumption that Homer was an Egyptian, and tranſferred Egyptian ideas into Greece and Aſia Minor. The dewy Lotus joins alſo with the Crocus and the Hyacinth to form a ſoft and thick genial couch for Jupiter and Juno.

Τωτε δ' υπο Χθων ερεπτο νεοθηλεα ποιην,
Λωτον τ' ηδε κροκον, ηδ' ακινακα βαθυν
Πιοσιον θ' υακινθον [d].

It was uſed alſo for making garlands [e].

The tree Lotus was no leſs famous than the herb. It gave name to a people, and is celebrated by Homer for extraordinary qualities [f]. Virgil ſpeaks of it with the Elm, the Willow, and the Cypreſs [g]; and Theophraſtus places it between the Cedar and the Cypreſs [h]. It is commonly ſuppoſed to be the Zizyphus or Jujube-tree (Rhamnus Zizyphus, Linn.), or perhaps more probably the Nabca of the Egyptians, Rhamnus Spina Chriſti of Linnæus [i].

1. Root perennial. Stems ſeveral, decumbent] ſlender, a foot and half long, [round, ſimple or with a few branches at the baſe, having ſtiffiſh hairs ſcattered over them, preſſed cloſe to the ſtem. Leaves ternate: leaflets obovate, fleſhy, ſeſſile, even, the edge towards the top having hairs ſcattered over it. Stipules ovate, acute, even, longer than the petioles, the ſame ſize with the leaves. Peduncles axillary, ſolitary, twice as long as the leaves, round, commonly one-flowered, ſeldom two-flowered. Bractæ three-leaved, a little ſhorter than the calyx, the middle one longer than the others. Calyx oblong, even, hairy at the edge. Corolla large, yellow, with fleſh-coloured veins on the middle of the banner underneath, the wings of a deeper yellow, keel ſhort with a greeniſh tip. The legume has four longitudinal wings.

It differs from the third ſpecies, by its perennial root, by the ſmoothneſs and greater fleſhineſs of the leaves, by the floral leaflets being lanceolate and not like thoſe on the ſtem, and by the calyxes being leſs deeply cut. The ſecond ſort has the ſtems a foot long, whereas in this they are ſcarcely more than a finger's length; the leaves and calyxes in that are a little hairy, in this they are ſmooth and fat as it were; the appearance alſo and place of growth are different [k].

Native of many parts of Europe, on the ſea coaſt, as Sweden, Denmark, Sileſia, the South of France, the County of Nice, &c. Ray found it at the mouth of the Tiber.—Cultivated by Mr. Miller, in 1759. It flowers from may to october [l].

2. This is diſtinguiſhed from the preceding to which it is very nearly allied, by its procumbent ſtems, white pubeſcent, a foot long; its hairy leaves and calyxes. Leaves alternate, petioled: leaflets ſubſeſſile, cordate-obovate, blunt, terminated by a ſpinule, quite entire, bright green and ſmooth above, white and ſilky underneath. Stipules large, cordate. Flower ſolitary, terminating, large, pale yellow, ſubſeſſile, ſurrounded by lanceolate ternate leaflets. Banner roundiſh, blunt, entire, keeled, ſpreading: wings blunt, converging, ſhorter than the banner: keel ſhorter than the wings [m]. Legume coriaceous, round, ſmooth, with a double narrow membranaceous wing not waved to each future, many-celled, two-valved: partitions ſpongy-membranaceous, ſnowy white, permanent. Seeds about twenty-four, ſubglobular, ſlightly compreſſed, ſmooth, with dark ſtreaks and dots in cluſters on a pale yellow ground. Albumen none or very ſmall. Embryo curved, yellow. Cotyledons ovate, thick, flatiſh. Plume none. Radicle inflex, centrifugal [n].

Native of the South of Europe, in moiſt meadows. I gathered it near Lancy, Vevay and Aigle, in may 1779.—Cultivated in 1683, by Mr. James Sutherland [o]. Our Gerarde calls it horned or codded Claver. Parkinſon, ſmooth codded Trefoile of Mompelier.

Monſ. Gerard and Leyſer do not diſtinguiſh this from the preceding. Magnol, who firſt ſeparated the ſea from the meadow Lotus, ſays that the latter has ſmooth fat thick leaves, and narrower pods.]

3. Root annual. Stems ſeveral, decumbent, (upright) about a foot long, having at each joint a ternate leaf. Leaflets ovate. Stipules of the ſame ſhape. Peduncles axillary, alternate, from two to three inches long, each ſuſtaining one (ſometimes two) large red flower at the top, with three leaves juſt under the flower. [The wings are very dark purple appearing to be black at the end. Legume thick, with four broad undulating wings. Seeds ſubglobular, the ſize of a ſmall pea, ſmooth, pale or livid purple, without ſpots [p].]

It flowers in june and july, and the ſeeds ripen in autumn. It was formerly cultivated as an eſculent plant, for the green pods, which are ſaid to be ſtill eaten in ſome of our northern counties, but they are very coarſe. This plant is now chiefly cultivated in flower-gardens for ornament. It is a native of Sicily, [where Ray found it on the hills above Meſſina: and was cultivated in 1596, by Gerarde [q]. Parkinſon calls it Crimſon-bloſſomed or ſquare-codded Peaſe. In Johnſon's edition of Gerarde's Herball it is named Square crimſon-velvet Peaſe. Ray calls it Square Codded Vetch. None of theſe authors ſpeak of the pod's being eſculent. Cluſius ſays the ſeeds were frequently ſent out of Italy under the name of *Sandalida*, which Adanſon has adopted for the generic name of theſe winged Lotuſes, and Scopoli for the trivial of the ſecond ſpecies.

4. This agrees with the preceding in habit, age, leaves, hairineſs and legumes; but differs in the corollas being only half the ſize; the legumes in pairs, with the wings entire and leſs waved or curled; and the leaves not embracing the ſtem at the baſe, but gaping on the oppoſite ſides [r].]

The ſtems are branching and a foot long; the leaflets are acuminate; the corollas are yellow, and the legumes are near two inches in length. It flowers in july, and the ſeeds ripen in the autumn.

[Native of France about Montpelier. Cultivated in 1759, by Mr. Miller [s].

5. Stems filiform. Corolla yellow with the back of the banner dark purple. It is diſtinguiſhed from all the other ſpecies by its ſolitary ſtipules and one-leafed bractes. The former are lanceolate-oblong, and the latter ſometimes, but ſeldom two-leaved [t].

[a] Jaſſieu. [b] Nymphæa Lotus, Linn. [c] Il. l. 3. [d] l. 14. 347. [e] Theocr. idyll. 18. Ovid. metam. l. 4. [f] Odyſſ. l. 9. See Pliny. l. 13. c. 17. [g] Georg. 2. 85. [h] Hiſt. l. 1. In the Supplement, it is faid to be a native of Majorca, if the plant there deſcribed be the ſame with that in Syſtema Vegetabilium.]

6. This is an annual plant, with ſeveral trailing ſtalks, a foot long. At each joint is a ternate leaf with roundiſh leaflets. The flowers ſtand ſingly on long axillary peduncles: they are yellow and ſmall, and are ſucceeded by thick pods, arched with a deep furrow on the outſide.

[The plant is almoſt that of L. tetragonolobus. Stem ſubvilloſe. Leaves ſmooth. Stipules ovate. Peduncles long, with three ovate bractes, the length of the flower. Legumes like thoſe of Crotalaria, ovate-oblong, gibbous, but with the dorſal ſuture ſtraight.

Native of Italy and Candia. Mr. Ray ſays that he met with this, or one very like it about Naples and in Sicily. Mr. Miller, who cultivated it in 1759[a], had the ſeeds ſent him from Nice. The pods are eaten in Candia, when young, by the poorer inhabitants[b]. It flowers here in July, but the ſeeds do not ripen in cold ſummers.

7. This is an annual plant like the eleventh, but doeſnot branch ſo much; the leaflets are rounder at their ends and ſmoother; the peduncles are ſhorter, and ſeldom ſuſtain more than two flowers; they are ſucceeded by two very narrow pods about two inches long, and hanging downwards.

[Native of the South of Europe.] Mr. Miller ſays Spain and Portugal. [Cultivated here in 1713. It flowers in July[c].

8. Root weak, branched. Stems ſtraight, numerous, a foot high, branched, reddiſh, beſet with long whitiſh hairs; at each joint a ternate leaf; leaflets oblong, acute. Peduncles axillary, ſolitary, an inch or more in length, with a yellow flower or two at top, in hairy calyxes. Legumes generally one, very ſeldom two[d]; ſlender, near two inches in length, obſoletely toruloſe where the ſeeds are: theſe are twenty or even twenty-three in number, ſpherical, pale ſulphur-coloured, very ſmooth, ſhining like pearls, the ſize of a pins head[e].

Native of the South of France. Mr. Ray gathered it near Naples. Mr. Miller has confounded this with one of the varieties of L. Corniculata.

9. Native of Madeira, where it was found by Mr. Francis Maſſon. Introduced in 1777. It is biennial, and flowers from june to auguſt[f].

10. Root perennial. Stems ſeveral, a foot and half high, ſcarcely pubeſcent. Leaves ternate, petioled: leaflets ſubpetioled, obovate, bluntiſh, ſomewhat hoary, almoſt ſmooth. Stipules almoſt of the ſame ſize and form with the leaflets. Petioles very ſhort. Peduncles erect, two, three, or four-flowered, often twice or thrice as long as the leaves. Flowers pedicelled, nodding, pale rufeſcent, with red veins on the banner; wings including the keel. Teeth of the calyx awl-ſhaped, diſtant. Bracte at the baſe of the proper peduncles, one-leafed, upright, like the leaflets. It ſleeps during the night with the flowers cloſe to the common peduncle, the bracte over it, the leaflets and ſtipules converging. Legumes cylindric, ſmooth, awned.

Native of Arabia, where it was found by Forſkahl, and in Suratte by Brad[g]. Introduced in 1773, by Chevalier Murray. It flowers from july to november[h].]

11. This is an annual plant, which ſends up many ſtiff ſtalks from one to two feet high, dividing into many branches. Leaves ternate with two appendages or ſtipules. Peduncles axillary, two or three inches long, terminated by a cluſter of yellow flowers.

[Theſe ſleep during the night with the bractes covering them. Stems even, from upright diffuſed. Leaves ſmooth, obovate or rhomb-ſhaped. Legumes three to five[i]; linear-oblong, ſickle-ſhaped, compreſſed, toruloſe or knobbed at the ſeeds; which are about fifteen, lens-ſhaped, ſhining, yellow or cheſtnut coloured, the ſame ſize with thoſe in L. ſiliquoſus[k].]

Native of Sicily. It flowers in july, and the ſeeds ripen in autumn. [Cultivated in 1683, by Mr. James Sutherland[l]. It was found by Ray on the hills above Meſſina, and at Capo Paſſaro. By Gerard, Sauvages, &c. in Provence, and by Pallas in Siberia.]

12. Stem ſlender, woody, from two to three feet high, ſending out many ſlender herbaceous branches. Leaves ſeſſile, hoary; leaflets narrow, white. Flowers axillary from the upper part of the ſtem, four or five on very ſlender peduncles, of a yelloviſh deep purple colour. Pods taper, ſlender, little more than an inch long, containing five or ſix ſmall roundiſh ſeeds.

[The leaflets are lanceolate-linear. Flowers from three to five together, the ſame colour as in Antirrhinum trifle, or a very rich brown-purple. The petiolets are white[i].

Native of the Cape Verd iſlands. Cultivated in 1714, by the Dutcheſs of Beaufort at Badminton[k].]

It flowers all the ſummer and autumn, and many times great part of the winter. Mr. Miller ſays that he had the ſeeds from the Cape of Good Hope.

13. This riſes with ſlender ſtems which require ſupport, from three to four feet high, ſending out a few ſide branches. At each joint is a neat ſilvery ternate leaf, with two appendages (or ſtipules). Peduncles axillary, from two to three inches long, ſuſtaining heads of yellow flowers, which part in the middle, each head containing four or ſix flowers. Theſe appear in may, june and july, and are ſucceeded by long taper pods filled with roundiſh ſeeds, which ripen in the autumn.

[It is a ſuffruticoſe weak plant, the whole of it ſilky with cloſe-preſſed hairs. Flowers uſually, in threes. Legumes oblong, cylindric, pendulous[l].

Native of Spain and the Levant. Cultivated in 1696[m]. Morilon had ſeeds from Aleppo, which produced plants at Oxford, before 1680.

14. Root annual. Stems a palm and half in height, round. Stipules ovate-lanceolate, awned. Leaflets firm, thick, obovate, emarginate, on a petiole about the length of the leaves. Peduncles axillary, much higher than the leaves, with one leaf on them, commonly one-flowered, ſeldom two-flowered. Flowers yellow, ſmall. Legumes erect, an inch long. Near Villafranca in the County of Nice, on the ſea coaſt[n].

15. Native of New Zealand[o].]

16. This has a perennial ſtalk three feet high. When the roots are large, they frequently ſend up ſeveral of theſe ſtalks, eſpecially if the old ones be cut down; they are hairy, and divide into ſeveral branches. Leaves ternate, hoary, with two ſtipules. Flowers in heads on long axillary peduncles. Calyxes very hairy. Corollas dirty white with a few marks of pale red. Pods ſhort, thick, cheſtnut-coloured, containing ſeveral roundiſh ſeeds.

[Stems a foot high, hard and woody. Leaves covered with long hairs, diſtinct and decumbent. Corolla reddiſh white, in a reddiſh calyx. Legumes ſwollen, blackiſh, ſhort, elliptic[p]. Flowers fewer than ten in a head, larger than the leaflet[q].

John Bauhin ſays it is from half a yard to a yard in height, and Magnol obſerved it in a wood a yard and half high. Several of the ſpecies are very ſhort in open ſituations, but are drawn up very much when they grow among buſhes.

Native of the South of Europe, as the ſouth of France, Italy, Sicily; alſo of the Levant. It was cultivated in 1683, by Mr. James Sutherland, and flowers from june to auguſt[r].

It is called by Gerarde Hoary Claver; and by Parkinſon, Greater Pile Trefoil.

17. This is a middle ſpecies between the preceding and following, inſomuch that it is difficult to ſay which it approaches the neareſt. Stem annual, but more ſpreadingly branched. Flowers white, leſs than in *hirſutus*, larger than in *reflus*. Legumes ovate.

This differs from all the reſt in having quinate (not ternate) leaves; that is, five leaflets, beſides the ſtipules; which are oblong, as in *L. hirſutus*, not cordate, as in *L. reflus*.

Native of the Levant, Greece, Arabia.]

18. This has a ſtrong perennial root, from which ariſe many upright ſtrong ſtalks, from three to four feet high, covered with a purpliſh bark, and towards the top ſending out a few ſide branches. At each joint is a ternate leaf, with wedge-ſhaped leaflets, and at the baſe of the foot-ſtalk two heart-ſhaped ſtipules, ſitting cloſe to the branch. Leaflets hairy on their under ſide. Flowers at the end of the branches in almoſt globular heads, ſitting cloſe to the pedunclc. Corolla pale fleſh-colour, appearing in June. Pods almoſt an inch long, changing to a brown colour when ripe, and containing ſeveral roundiſh ſeeds, which ripen in ſeptember.

[Stem ſuffruticoſe, from two to three feet in height. Flowers whitiſh, numerous, in a horizontal bundle. Legumes more than twenty, whereas in *L. hirſutus* there are fewer than ten[1]; they are cylindrical, obſolctely torulooſe at the ſeeds, black, the length of the human nail, and contain ſix or eight, ſmall, globular, black ſeeds, which are not ſhining[2].

Native of the South of Europe; obſerved in the South of France, Calabria, and Sicily, by Ray; in Aragon, by D'Aſſo; near Lyons, Turin, &c. by Moriſon; in the County of Nice, by Allione. Parkinſon calls it Lesſer Pile Trefoil.—It was cultivated in 1683, by Mr. James Sutherland[3].]

Mr. Miller ſays, this has by ſome been ſuppoſed the Cytiſus of Virgil, but without foundation; that cows and horſes will eat it when green, but that he had not tried if they will feed on it when made into hay.

19. Root perennial, tapering, ſtriking deeply into the earth. Stems ſeveral, ſlender, bluntly four-cornered, procumbent except where ſupported, as in meadows or among buſhes, from ſix or ſeven inches, to a foot and half in length; varying even more in different ſoils and ſituation, and in the ſeveral varieties. I have now before me (Auguſt 17th, 1797) ſpecimens from the ſame ſpot, ſome growing detached perfectly procumbent and only ſix inches long, other three feet and a half high, by having run up among buſhes, which they do without either twiſting or claſping by tendrils. Leaves ternate, petioled, one at each joint, the leaflets differing extremely in form, in the ſeveral varieties, from bluntly ovate to linear-lanceolate; thoſe in the ſpecimens before me are ovate, terminating in a ſhort point, on very ſhort pedicels, the middle one narrowing towards the baſe, ſo as to be almoſt wedge-ſhaped, they are ſmooth, and the common petiole is membranaceous. The ſtipules reſemble the leaves, but they are more pointed, and are rather lanceolate than ovate. The flowers grow in flatted heads reſembling umbels, on pedunclcs from two to three inches and a half in length, but on pedicels hardly a line long. There is a ſingle ſeſſile ternate leaf at the baſe of each head without any ſtipules; and ſometimes there is only one leaflet or two: the number of flowers varies from three or four to twelve or thirteen; none of my ſpecimens have more than ſix, very few more than four, and ſome only one or two. Calyx fringed with long ſoft hairs. Corolla, before it opens, of a bloody red on the outſide, and of a yellowiſh green within; when expanded of a full yellow, all the petals are equal, and ſtand each on narrow ſeparate claws; the banner bent back, and the wings oblong-ovate. Legumes ſmooth, ſpreading like the ſpokes of a wheel, or rather like the fingers, or bird's claws, and ending in a long ſtraight point. Seeds many, ſometimes more than twenty, ſmall, ſomewhat kidney-ſhaped, and ſpotted[4]. I do not find that more than three or four pods in a head come to maturity.

Native of all parts of Europe, and alſo of Japan, in meadows, paſtures, heaths, by road-ſides, in hedges, among buſhes, and in woods; flowering from june to auguſt. The ſimilitude of the ſtipules to leaves occaſioned ſome of the old writers to call it Lotus pentaphyllos; Gerarde however calls it Small Codded Trefoil; and Ray, Bird's-foot Trefoil, which is the name now commonly retained. Withering calls it Bird's-foot Clover. In Yorkſhire it is ſaid to be called Cheeſecake Graſs, and in ſome other counties, Butterjags, and Crow-toes. It has been recommended for cultivation by Ellis under the name of Ladies fingers[5], by which it is confounded with Anthyllis Vulneraria, a much inferior plant in rural economy; and by Dr. Anderſon under the name of Astragalus glycyphyllos, or Milkwort, which is a ſtrong-ſmelling ſticky plant, that does not ſeem to be agreeable to cattle, though Linnæus affirms that herſes, kine, goats and ſheep eat it.

In German it is named *Gehornte Schotenklee, Wilder Steinklee, Gelber fünfblattriger Klee, Gehörnt Klee, Gelbe Vogelwicke, Gelbe Schoten, Kleiner gelber Hauklee, Kleiner Hornklee, Hornwicke, Waldzeekraut, Frauenfingerkraut, Unſerer Lieben Frauen Schuhlein.* In Dutch, *Gehoornde Klaveren, Gekroonde Muiten, Jaffersſchoentjes.* In Danish, *Kiernringstand, Krageklover.* In Swedish, *Karingetander.* In French, *Le Lotier cornicule, ou des prés, Treſle jaune.*

Mr. Miller has made three ſpecies out of this: 1. Lotus corniculatus; the common ſort. 2. L. anguſtiſſimus, which he ſeems to have confounded with our eighth ſpecies. 3. L. glaber, variety γ of this.

The uſual appearance of Common Bird's-foot Trefoil has been deſcribed above.

β. Has the ſtem more upright, a foot high, hardly angular. Leaves and eſpecially the unexpanded heads with a good deal of wooſlineſs. Leaves veined underneath. Stipules bluntly ovate or roundiſh, but terminating in a point[6].

Scopoli diſtinguiſhes this ſpecifically from the common ſort, by the form of the leaves and braſtes (or ſtipules). In that, as he affirms, the leaflets are ovate, and the ſtipules ſemicordate; in this, which he calls Lotus major, both leaves and ſtipules are lanceolate. But the ſtipules are not ſemicordate in our Common Bird's-foot Trefoil.

This greater variety is found in woods, moiſt meadows, hedges, and the ſides of wet ditches.

γ. In this variety the ſtems are twice as long and narrow as in the common ſort. The leaves and ſtipules are alſo very narrow, and almoſt linear. Legume narrower. It is more ſhrubby than the common. Corn fields and moiſt places. Near Worceſter[7].

δ. This reſembles β, but is leſs hairy. The whole plant is downy. Mr. Doody found it in the fields behind Mother-Huſſs.

ε. Leaves hoary underneath. Found in the chalk-pits at Greenhithe by Mr. Doody[8].

ζ. Entirely without hairs. Stipules half-ovate. Filaments club-ſhaped. On the high grounds north of Marlborough in june[9].

But Monſ. Villars juſtly calls this ſpecies a Proteus, and remarks that he has ſeen individuals of the great hairy variety, that approached nearer to Lotus hirſutus, in appearance, than to many individuals of this ſpecies. Where plants are ſo given to change, it is eaſy, but dangerous to multiply ſpecies. I am ſurpriſed that Linnæus, in diſtinguiſhing the firſt and ſecond ſpecies, ſhould mention that the appearance and place of growth are different, when the place of growth may probably occaſion the difference in the appearance.

The flowers of Bird's-foot Trefoil become green when dried, in which reſpect they reſemble thoſe of Indigo[10].]

Mr. Miller ſays, he has always obſerved, that cattle of all ſorts avoid eating this plant, whilſt the graſs all round it has been eaten very bare. [But he ought to have remarked, that it is the deſignation of Providence, that whilſt cattle crop the herbage, they generally leave the flowering ſtems untouched, otherwiſe many plants could not be propagated. When he goes farther indeed, and affirms] that he has cut the plant when young, and given it to various animals, but could never get them to eat it; [we can only ſay that more modern experience contradicts his experience, whatever

[1] Villars. [2] Gaertner. [3] Hort. kew. [4] Curtis, Woodward Mſs. Withering Fl. ruſtica.

[5] Ellis, Chiltern and Vale Farming, 291. [6] Withering. [7] Lion. Wither. Ray. [8] Ray syn. [9] Withering. [10] Jolli.

ever it might be. Linnæus's account is, that kine, goats and horſes eat it, but that ſheep and ſwine are not fond of it. On the contrary we are told that it is cultivated in Hertfordſhire as paſturage for ſheep. It makes extremely good hay; in moiſt meadows grows to a greater height than the Trefoils[1], and ſeems to be of a quality equal, if not ſuperior to moſt of them. In common with ſeveral other leguminous plants, it gives ſubſtance to the hay, and perhaps contributes to render it more palatable and wholeſome for cattle.

Dr. Anderſon affirms, that as every ſpecies of domeſtic animal eats the Bird's-foot Trefoil, (or Milkwort, as he calls it, having miſtaken it for Aſtragalus glycyphyllos, a plant totally different in appearance, character and qualities;) in preference to every other plant, it ſeldom comes to flower in paſture grounds, unleſs where they have been ſaved from cattle for ſome time. What firſt recommended it to his notice, was the having obſerved it to grow and flouriſh in poor ground; as in the midſt of a barren moor, where the ſoil was ſo poor that even heath could hardly grow: upon bare obdurate clays: in dry and barren ſands. It certainly flouriſhes not only in theſe, but alſo in a chalky ſoil: and we may add, that on moors, heaths and downs hard ſtocked with ſheep, we may obſerve the ſurface to be yellow with the flowers of this plant; which contradicts what Dr. Anderſon aſſerts above, that it ſeldom comes to flower in paſtures; without however confirming the aſſertion of Linnæus, that ſheep diſlike it, or of Miller, that no cattle will eat it: for they devour the herbage, though they leave the flowering-ſtalks untouched, as we remarked above. Dr. Anderſon's figure is not exact in the leaves, there being always three leaflets with two ſtipules, whereas he has never more than four, and frequently only two[2].]

20. This is a perennial plant, ſending out from the root many ſtalks, which branch out their whole length. Leaves ternate, with two appendages or ſtipules, both covered with a woolly down. Flowers on ſhort peduncles, four or ſix in a divided head; they are yellow and appear in july. Pods taper, with roundiſh ſeeds, ripening in autumn.

[Native of the South of Europe, on the ſea coaſt. Cultivated in 1752, by Mr. Miller[3].]

21. This riſes with weak ſhrubby ſtalks three or four feet high, ſending out many ſlender branches, thinly ſet with ſmall hoary leaves, having five leaflets, ſpreading like the fingers, and ſeſſile. Flowers at the extremity of the branches in ſmall heads. They are very ſmall and white, appear at the end of june, or in july, continue to ſeptember, and are ſucceeded by ſhort pods, containing two or three ſmall round ſeeds.

[Native of the South of Europe. Cultivated before 1640, by Parkinſon[4].

Vahl remarks, that there are many ſpecimens in the herbariums of ſeveral botaniſts, ſo different, that they are probably diſtinct ſpecies.

Almoſt all the old writers, ſome of the moderns, and Linnæus himſelf in his earlier works, made the Dorycnium a diſtinct genus. Monſ. Villars ſays it forms a genus between Lotus and Trifolium, differing from the former in the ſhortneſs of its legume, its woodineſs, its diſtinct and more regular leaves, its calyx and very ſmall flowers. It would range better with the Trefoils, if it were not an abſurdity to ſpeak of a Trefoil with quinate leaves, and if that genus were not much loaded with ſpecies already. He makes two ſpecies of Dorycnium. 1. D. ſuffruticoſum; with ſuffruticoſe, upright ſtems. 2. D. herbaceum, with a diffuſed, herbaceous ſtem. The firſt has woody ſtems, branched at bottom. Leaves narrow, oblong, whitiſh, as is the whole plant. Corolla white, except the keel, which is violet. Each pedunele has a ſimple leaf, a little below the flowers.—The ſecond has the ſtems ſtraight, round, villoſe, herbaceous, branching at their upper part; the branches very ſtraight, and approximating to the ſtem, which is from two to three feet high. Leaves by fives, without any petiole, oblong, blunt, widening at the upper part, and ending in a rounded point. Flowers white and ſmall as in the firſt, but double the number. Calyx a little more lengthened, ending in five points, that are more regular than in the firſt.

Native of Dauphiné about Grenoble, and of Savoy near Chambery.

This plant is uncommon and perhaps unknown. It has the habit and ſize of *Lotus veſtus*, with the character of *Dorycnium*. Cluſius's figure, copied by Lobel, John Bauhin, Parkinſon, &c. may ſerve to repreſent this as well as the firſt. Dalechampius's alſo repreſents it, but the leaves are much too narrow[5].

22. Root annual. Stem proſtrate, grooved, rough-haired. Leaves ternate, on long petioles, obcordate, toothletted, ſmooth, marked with lines. Stipules ſemiſagittate, entire, with a two-toothed lobe at the baſe. Pedunckes axillary, elongated, five or ſix-flowered, umbelled, with ſmall yellow flowers. Legumes four to ſix, linear, bowed, toruloſe.

Native of Siberia, reſembling Medicago polymorpha when in flower, but ſmaller, with the legumes of Trigonella. Doubtful whether it be of this genus, or a Trigonella[6].

23. Root annual. Stems from aſcending upright, branched, villoſe, half a foot or more in height. Leaves ternate, obconical, the midrib ending in a ſpinule, pubeſcent. Stipules pedicelled, ſubovate, acuminate, villoſe, ſmaller than the leaves. Pedunckes ſolitary from the upper axils, moſt frequently two-flowered, ſupported by a three-leaved bractæ. Calyx villoſe, græniſh yellow ſpotted with red, the middle tooth of the lower lip longer and larger, but the upper ones equal. Corolla yellow, not longer than the calyx: banner erect, ſubovate, marked with five red lines, the ſide ones uſually two-parted and paler: wings longer than the keel, cohering at top, concave, elliptic, with a blunt eardet from one ſide of the baſe: keel ſickle-ſhaped. Legume ſlightly ſickle-ſhaped, an inch and half long. Seeds ſometimes as many as twenty-two, round, yellow, lucid, ſeparated by membranaceous partitions.

It approaches to L. anguſtiſſimus, but the ſtem is upright. It differs from L. Cornuculata in the ſtems, floreſcence, life, &c. The legume alſo is not one-celled; nor are the ſeeds cylindric but ſpherical. The ſeeds were ſent by Allione. It flowers the beginning of july (in Italy) and perfects the ſeeds by the end of that month[7]. This ſpecies ſhould have been placed in the firſt diviſion.

The determination of the foregoing ſpecies may be aſſiſted by the following table, aſſiſted by the ſpecific characters.

- Perennial. 1. 2. 5. 10. 12. 13. 15 to 21.
- Biennial, 9.
- Annual. 3. 4. 6. 7. 11. 14. 22. 23.

Stem
- Arboreous. 15.
- Fruteſcent or Suffruteſcent. 12. 13. 16. 17. 18. 21.
- Herbaceous, *the reſt*.

Leaves
- Quinate. 17. 21.
- Ternate, with two ſtipules; *the reſt*.

Legumes
- Few. 1 to 15.
  - Square, winged. 1. 2. 3. 4.
  - Cylindric. 5 to 23.
    - *One.* 1. 2. 3. 5. 6. 8. 9. 14. Some have ſometimes 2.
    - Two. 4. 7. 23.
    - Three or Four. 10.
    - Three to Five. 11. 12. 13.
    - Five. 15.
- Many in heads. 16 to 22. Some not more than 4 or 5.

Seeds
- Ovate. 1 to 4. 23.
- Cylindric. 5 to 22.

Corolla
- Red. 3.
- Deep purple. 12.
- Reddiſh white. 16.
- Pale ruſeſcent. 10.
- Whitiſh or pale Fleſh-colour. 18.
- White. 17. 21.
- Yellow, in all the reſt.

PROPAGATION AND CULTURE.

1. 2. 4. 6. 7. 11. 20. These are propagated by seeds, which should be sown early in april upon an open bed or border exposed to the sun, where the plants are to remain: when they come up they must be thinned, leaving them near two feet asunder, and afterwards they must be kept clean from weeds, which is all the culture they require.

3. The Winged Pea is an annual plant commonly cultivated in flower-gardens for ornament. The seeds are sown in patches, five or six together, where they are designed to remain. If the seeds all grow, some of the plants may be pulled up, leaving only two or three in each patch, and afterwards they will require no other care but to keep them clean from weeds.

12. This is too tender to live abroad, the plants therefore are kept in pots, which in winter are placed in a warm airy glass-case or dry stove, but in summer are placed abroad in a sheltered situation. It may be easily propagated by cuttings during the summer season, and also by seeds; but the plants which have been two or three times increased by cuttings, are seldom fruitful. [The plants are subject to go off at once, and therefore new ones should be constantly raised, especially as this is a very beautiful sort, and almost always in flower.]

13. This also is too tender to live in the open air, and therefore must be treated like the preceding. It may be increased by seeds, sown on a bed of light earth in april. The plants will come up in about a month, and in another month will be fit to remove; when each should be put into a separate small pot filled with fresh light earth; placing them in the shade till they have taken new root: then they may be removed to a sheltered situation, where they may remain till autumn.

It may also be propagated by cuttings, planted during any of the summer months, upon a bed of light earth, covering them close with a bell or hand-glass, and screening them from the sun; in five or six weeks they will have taken root, when they must be inured to the open air, and soon after may be planted in pots, and treated in the same way as the seedling plants.

16. This is propagated by seeds in the same manner as the last sort: the plants will live through the winter in the open air in moderate winters, but it will be proper to keep one or two plants in pots to be sheltered in winter, lest those abroad should be destroyed by severe frost.

18. This sort may be cultivated for feeding cattle in the same manner as Lucerne. It rises easily from seeds, is very hardy, and will thrive on any light dry poor ground.

[19. Dr. Anderson sowed the Common Bird's-foot Trefoil with his ordinary hay-seeds. It grew the first season as tall as the great Clover, and was scarcely distinguishable from Lucerne, but by the slenderness of the stalk, and proportional smallness of the leaf. Like Lucerne, it is perennial, sends down a long root to a great depth, at first small, but becoming at length of a considerable size: so that it is several years before it attains its full perfection: but when once established, it remains many years in full vigour, and produces annually a great quantity of fodder. In autumn 1773, he cut the stalks from an old plant in an indifferent soil, and having dried it, found that it weighed fourteen ounces and a half. Like Lucerne it is never affected with the severest drought; but it does not resemble that plant in delicateness of constitution; as it thrives in the stiffest clays, and stands its ground among grass and weeds. The stalks die down entirely in winter, and do not come up in the spring till Clover begins to advance, so that it can never be of use but as a summer pasture. Neither does it advance very fast after it is cut down, or eat over, even in summer.

Dr. Anderson speaks of the larger variety, which he calls another species of Astragalus, with an erect stalk, that naturally grows upon dampish soils. He thinks it more likely to answer well for hay, the stalks being longer; but had no opportunity of making particular observations on it, or of procuring the seeds[a].

Mr. Curtis justly remarks; whether this plant be deserving of the encomiums here bestowed upon it, the practical farmer must determine. There appears no reason, why seed might not be obtained from it; and it should seem that land not strong enough to bear Clover might be improved by the introduction of Bird's-foot Trefoil.

August 18th 1797. I gave a handful of it in full flower and seed to a working horse, who eat it greedily in preference to very good hay on which he was then feeding. A cow also in full pasture received it with seeming avidity.]

21. Dorycnium will live in the open air, if it be planted in a dry soil and warm situation. It is propagated by seeds, which will come up in any common border.

Camphorosma Pteranthus. *Lin. syst.* 166. *mant.* 41.

DESCRIPTION, *&c.*

This is an annual, very branching plant, a span high. Stem almost upright, round. Branches in whorls, the upper ones opposite, spreading very much; the lower ones prostrate, jointed, knobbed: branchlets in pairs from each axil. Leaves six, in whorls, the two outer opposite ones larger, the four inner from each side of the axils, the uppermost seldom only opposite, sessile, linear, quite entire, scarcely one-nerved, very smooth, thickish, bright green, the same colour on both sides, from six to eight lines in length, and one or two lines in breadth. Flowers terminating, coming out successively, sessile, close, the middle ones solitary, herbaceous, two or three lines broad.

See Camphorosma, from which it differs in habit, in having a common receptacle, and in the stamens, being monadelphous[b].

DESCRIPTIONS, &c.

1. This is an annual plant, riſing with an upright branching ſtalk a foot high. The flowers come out ſingly at the axils. Flowers ſmall, on ſhort peduncles. Corolla yellow.

[Capſule ſhorter than the permanent calyx, from a rounded baſe cubical, opening at the angles: partitions membranaceous, inſerted on one ſide into the middle of the valves, on the other into the axis, not ſeparating. Receptacle a compreſſed, fungoſe lamina or plate, fixed to the inner angle of each cell, covered on both ſides with the ſeeds; which are ovate, ſmooth, ſomewhat ſhining, pale yellow[1].

Native of Virginia[2]; or according to Mr. Miller, of South Carolina, whence the ſeeds were ſent him by Thomas Dale, M. D. [before 1752. It flowers in June and July[3].

2. Stems procumbent, a ſpan long. Branches at the root, and ſcarcely any others. Leaves ſmooth, quite entire, ſtriated, ending in the petioles. Flowers ſolitary, axillary. Corolla yellow, ſhorter than the calyx. Germ longer than the calyx. Capſule ſhorter by half than the leaves[4].—In Flora zeylanica the leaves are ſaid to be *alternate*; the herb like Lythrum hyſſopifolium, and the flower in the form of Caryophyllus officinarum. Native of the Eaſt-Indies.

3. This is an annual plant, native of Jamaica[5]. See *Iſnardia paluſtris*, which is the ſame.

4. This alſo is annual. Stem herbaceous, a foot high, brachiate, ſmooth. Leaves petioled, quite entire, ſmooth. Peduncles terminating, about three together, one-flowered; ſeldom axillary. Germs four-cornered, winged. Calyxes minute. Corolla ſcarcely viſible. Capſule ſubcubical, with the four angles keeled. Native of the Eaſt-Indies[6].

Juſſieu doubts whether this ſpecies belongs to the genus; the leaves being oppoſite, and the flowers terminating[7].]

PROPAGATION AND CULTURE.

The plants muſt be raiſed from ſeed in a hot-bed, in the ſpring, and treated as directed for Amaranthus. If they be not brought forward in the ſpring, they ſeldom produce good ſeeds in England.

DESCRIP-

DESCRIPTIONS, &c.

1. This is a very large plant. Root perennial, white. Stem from three to four feet high, upright, ſimple, channelled, green tinged with purple, hirſute. Lower leaves oppoſite, upper alternate, on long petioles, ſmooth or rough-haired, cordate, unequally ſerrate, nerved, acuminate, near a ſpan long, and three or four inches wide. Flowers terminating, on long ſlender peduncles, often bifid and trifid. Calyxes of a white purple colour, and ſmooth. Petals purple, odorous. Silicles acuminate, an inch and half wide, three inches long, with the permanent ſtyle half an inch in length. They contain three, four or five roundiſh ſeeds faſtened to the margin of the future by a thread. The flowers have two glands on each ſide between the longer ſtamens and the ſtyle, and one between the ſtyle and each ſhorter ſtamen[1]. This circumſtance accounts for the bagging of the perianth. Native of the South of France, Italy, Switzerland, Silelia, Auſtria, Hungary.—Cultivated by Gerarde in 1597[2].

2. Root biennial, knobbed. Stem ſmaller than the preceding, upright, branched, hirſute, round, half a yard high. Leaves rough-haired, the floral ones almoſt alway; oppoſite, ſeſſile: ſtem-leaves petioled, much ſmaller than thoſe of the preceding, cordate, dull green, ſerrate. Calyx purpliſh aſh-colour, hirſute. Petals violet or blue-purple, inodorous. Style two lines long, permanent. Silicles broader, blunter, ſhorter. Seeds five or ſix[3].

Native of Germany. Cultivated in 1597, by Gerarde. They both flower in may and june[4].]

The ſeed-veſſels, when full ripe, become tranſparent, and of a clear ſhining white like ſattin, whence this plant has acquired the name of *White-Sattin*. The branches uſed to be dried and preſerved to place in chimneys. [Gerarde ſays it is called in Engliſh Pennie-flower or Money-flower, Silver-plate, Prick-ſongwoort, in Norfolk Sattin and White Sattin, and among our women Honeſtie. This laſt name now moſt commonly obtains, and I preſume is derived from the tranſparency of the ſeed-veſſels, in which the whole may be viewed, without deceit.—In German it is named *Mondviole*, *Mondkraut*, *Silberblume*, *Silberblatt*, *Flittern*, *Atlas-blume*, *Waldrioge*l. In Dutch, *Maankruid*, *Penninghruid*, *Zilverbloem*. In Daniſh, *Maanevioel*. In Swediſh, *Manefioler*. In French, *la Lunaire*, *Satinée*, *Satin blanc*, *Paſſe-ſatin*, *Medaille*, *Herbe aux lunettes*, *Bulbonac* (from its ſtrumous or glandular root.) In Italian, &c. *Lunaria*.

Gærtner regards theſe two ſpecies as one, and aſſerts that there is no true diſtinction between them beſides duration; that the colour of the calyx and corolla, or the odour of the flowers is nothing; and that Linnæus's ſpecific difference from the ſituation of the leaves is fictitious.

He deſcribes the Silicle as very large, elliptic, attenuated at top into the ſtyle, at bottom into the pedunclc, compreſſed, flat, two-celled, two-valved: partition like paper, white, parallel to the valves. Receptacle intervalvular, filiform, emitting on both ſides towards the centre umbilical threads, faſtened to the ſeptum. Seeds few, two or three, ſeldom four in each cell, large, ovate-kidney-ſhaped, compreſſed like a lens, with a broad membranaceous rim, at firſt reddith, then brown, with very minute dots on them.

If the ſpecies be diſtinct, they are certainly very nearly allied, and have been confounded. According to Linnæus, the root of the firſt is perennial; the flowers odorous; the leaves alternate except the loweſt, and more rough-haired. In the ſecond, the root is biennial; the flowers inodorous; the ſtem hirſute; the leaves oppoſite, at leaſt in the cultivated plant: but he queſtions whether it be ſo always. He makes the latter a native of Sicania; but it appears that it is the former which was found there. Gerarde, I know not by what miſtake, ſays that they are found wild about Pinner, Harrow, Watford and Hornchurch. Johnſon does not correct him: but Parkinſon ſays, he could never certainly be aſſured of it; and no one, that I have heard, has found them ſince.

Monſ. Villars is of opinion that the lengthened pointed form of the fruit, is ſufficient, independent of the duration, villoſe calyx, &c. to diſtinguiſh the firſt ſpecies from the ſecond, which is that moſt commonly cultivated in old flower-gardens.

I have a ſeedling plant of this now (Aug. 21. 1797) before me, which has ſeven full-grown leaves on it, and two young ones ſpringing from the centre. The former are of an oblong cordate form, from ſix to ſeven inches long, and five inches wide near the baſe, light green, villoſe on the upper ſurface, and rough-haired along the veins of the lower ſurface, which are very prominent; the edge is rather crenate than ſerrate: the petioles are ſeven or eight inches long, very rough-haired, and channelled.

A plant of the ſecond year, now in full ſeed, is five feet high; the ſtem round, ſomewhat flexuoſe, quite ſimple, having no branches but thoſe which produce the flowers: white pellucid hairs are ſcattered over it, and it is ſpotted with browniſh purple towards the bottom. The root-leaves are gone, having left only the withered petioles. The ſtem-leaves are ſolitary, alternate, cordate-oblong, almoſt ſagittate, drawn to a point, pale green, villoſe, the midrib and principal veins rough-haired, the edge unequally ſerrate, with larger and ſmaller ſerratures alternately: the loweſt leaves are nine inches in length, and ſix in breadth where the petiole is inſerted, which is three inches long: but this gradually ſhortens to about the middle of the ſtem, and then the other leaves to the top are ſeſſile: the uppermoſt leaf (or two) is even jagged. From each axil to within a foot of the bottom comes out a ſingle flowering ſtalk; the lower ones near a foot long, with a few leaves on them, like the ſtem-leaves, but ſmaller, ſometimes oppoſite, but more frequently alternate; theſe have but few flowers on them: the upper flowering-ſtalks are ſhorter, have no leaves, but more flowers: and a bunch or ſpike of flowers terminates the whole. Silicles alternate, broad-elliptic, an inch and half long, an inch and quarter broad, on pedicels above an inch and half in length; the permanent ſtyle three eighths of an inch long. The number of ſeeds is uncertain, from two or three to ſix or ſeven, but ſome of theſe are generally abortive. I do not diſcern any traces of that attenuation of the ſilicle which Gærtner ſpeaks of.

Mr. Miller has given the ſpecific differences right, from the ſilicles; but in his deſcriptions he has reverſed them; aſcribing large roundiſh pods to L. rediviva, and longer narrower pods to L. annua, which he ſays alſo has larger flowers, and of a lighter purple colour.

3. This is an annual plant, with a ſmooth branching ſtalk little more than a foot high. Leaves unequally pinnate: leaflets differing in ſize and form; ſome almoſt entire, others cut at their extremities into three parts; they are ſmooth, and of a lucid green. The flowers ſtand each upon pretty long ſlender peduncles, which come out from the ſide, and alſo at the end of the branches, in looſe ſmall cluſters; they are of a purple colour, and are ſucceeded by oblong compreſſed pods, which hang downward, and when ripe are of a *feuille-mort* colour.

[Silicle ovate-oblong or rhomb-elliptic, ſtarred like a leaf, two-celled, two-valved: partition parallel to the valves, thin almoſt as a cobweb, generally glued faſt to the valves when the ſeed-veſſel is ripe, ſo that it eſcaped Linnæus and others, who accordingly ſuppoſed the fruit to be one-celled. Seeds in each cell one or two, ſubcordate, or deeply emarginate at the umbilicus, compreſſed, ſomewhat rugged to the touch, obſoletely margined, brown.

There being certainly a partition in the ſilicle, this ſpecies ought not to be ſeparated from Lunaria, ſince there is ſuch a conformity in the fructification, although the outward habit be peculiar, and very different from the others[5].]

Native of Egypt. It flowers here in june and july;

[1] Krocker. Scop. Villars.
[2] Krocker.
[3] Hort. kew.
[4] Hort. kew.
[5] Gærtner.

the seeds ripen the beginning of September, and the plants decay soon after.

[It was cultivated in 1757, by Mr. Miller[1].]

PROPAGATION AND CULTURE.

1. 2. These are propagated by seeds sown in the autumn. Those sown in the spring often miscarry, or lie a long time in the ground. They will grow in almost any soil, but love a shady situation; and require only to be kept clean from weeds. If the seeds be permitted to scatter, the plants will rise without farther care; and if they be left unremoved, they will grow much larger than those which are transplanted.

3. Sow the seeds in an open border, where they are to remain: if they be sown soon after they are ripe, the plants will come up in the autumn, and live through the winter, in a sheltered situation: these will flower early the following summer, whereby ripe seeds may be obtained: they may also be sown in the spring. Keep them clean, and thin them where they are too close. If the seeds be permitted to scatter, these also will come up without care.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, bifid.

COR. papilionaceous. *Banner* cordate-roundish, emarginate, bent back at the sides, compressed. *Wings* subovate, almost the length of the banner, not fastened to the keel, converging below. *Keel* two-parted at the base, sickle-shaped upwards, acuminate, entire, the length of the wings, narrower.

STAM. *Filaments* ten, united, somewhat ascending, distinct above. *Anthers* five, roundish, and as many oblong.

PIST. *Germ* awl-shaped, compressed, villose. *Style* awl-shaped, ascending. *Stigma* terminating, blunt.

PER. *Legume* large, oblong, coriaceous, compressed, acuminate, one-celled.

SEEDS several, roundish, compressed.

OBS. *The calyx is different in the several species.*

ESSENTIAL CHARACTER.

Cal. two-lipped. *Anthers* five oblong, five roundish. *Legume* coriaceous.

[8. Lupinus cochinchinensis. *Single-leaved Lupine.*
Lour. cochinch. 429.
Calyxes appendicled in spikes, upper lip bifid, lower three-toothed, leaves simple, ovate.

9. Lupinus africanus.
Lour. cochinch. 429.
Calyxes appendicled five-cleft, peduncles many-flowered terminating, leaves ternate lanceolate, stem shrubby diffused.

10. Lupinus trifoliatus.
Cavan. hisp. 43. *n.* 65. *t.* 59.
Calyxes five-toothed, legumes in spikes upright, leaves ternate ovate, stem herbaceous.

DESCRIPTIONS, &c.

These are mostly herbaceous, annual plants. The leaves digitate, with stipules at the base of the petiole. Flowers in terminating spikes, either placed alternately, or in a sort of whorl; some naked, others bracted[1]. The first species is perennial; the ninth shrubby. The leaves are simple in the eighth, ternate in the ninth and tenth species. The flowers are white in the second sort, flesh-coloured in the fifth, yellow in the seventh, eighth and ninth, in the rest blue.]

[1] Juffieu.

1. This

1. This has a perennial creeping root, from which arife ſeveral erect channelled ſtalks a foot and a half high, ſending out two or three ſmall ſide branches, garniſhed with digitate leaves, compoſed of from five to ten or eleven narrow ſpear-ſhaped leaflets, which join at their baſe, and ſtand upon very long foot-ſtalks, having a few hairs on their edges. The flowers grow in long looſe ſpikes, which terminate the ſtalks, and are placed without order on each ſide; they are of a pale blue colour, and on ſhort peduncles. Theſe appear in june, and the ſeeds ripen in auguſt, which are ſoon ſcattered if they are not gathered when ripe; for after a little moiſture, the ſun cauſes the pods to open with elaſticity, and caſt out the ſeeds to a diſtance all round.

[Linnæus ſays that the leaves conſiſt of eight lanceolate blunt ſmooth leaflets; and that the flowers are placed alternately in very long racemes, commonly two together from one point, each on its proper pedicel. According to Miller, the number of leaflets varies much, and the flowers are either in pairs, or elſe three or four from the ſame joint.

It is a native of Virginia and other parts of North America; and was cultivated in the botanic garden at Oxford in 1658.

Kalm informs us that Perennial Lupine is abundant in the woods in New Jerſey, and that he has often found it thriving on very poor ſandy fields, and on heaths, where no other plants would grow. The flowers, which commonly appear there in the middle of may, make a fine ſhow by their purple hue. He was told that the cattle would eat theſe flowers very greedily, but found that they were not fond of this plant when they had any thing elſe. Horſes, indeed, eat the flowers, but left the ſtalk and leaves; and if cattle eat the plant in the ſpring, it was from neceſſity. However he is of opinion that the Perennial Lupine might be tried on dry ſandy heaths, and that means might be found to make it palatable to cattle.]

2. This has a thick upright ſtalk about two feet high, dividing towards the top into ſeveral ſmaller hairy branches. Leaves digitate, compoſed of ſeven or eight narrow oblong leaflets, joining at the baſe; they are hairy, of a dark grayiſh colour, and have a ſilvery down. The flowers are produced in looſe ſpikes at the end of the branches; they are white and ſeſſile. Legumes ſtraight, hairy, about three inches long, containing five or ſix ſeeds, [which are roundiſh, flatted like a lens, extremely ſmooth and even, perfectly white without any ſpots, ſmaller than moſt of the others. The umbilicus or navel has a prominent ring.] It flowers in july, and the ſeeds ripen in the autumn. It grows naturally in the Levant, and is cultivated in ſome parts of Italy, as other pulſe, for food. [Alſo in the ſouth of France, in poor dry extenſive plains, as a meliorating crop, to be ploughed in, where no manure is to be had, and the ground is too barren for clover or other better plants[a]. With us it is uſed only among other annuals in the flower-garden, and was thus cultivated by Gerarde in 1596. He ſays, it is named in Engliſh, Garden or tame Lupine, and of ſome, after the German name, *Fighoane*.

Ray, who has deſcribed this plant very well, remarks that the leaves, which are not unaptly named *digitate* by Jungius, have the ſides contracted at night, and hang down, being bent back to the petiole[b]. This was a phenomenon before the time of Linnæus very little attended to. He alſo obſerved the cultivation of the Lupine in Tuſcany, not only for food, but for improving the land by ploughing it in; a practice continued from the time of the ancient Romans, as may be ſeen by conſulting Pliny and Columella.]

3. This is an annual plant, with a firm, ſtraight, channelled ſtalk near three feet high, divided towards the top into ſeveral branches. Leaves digitate, compoſed of five, ſix, or ſeven oblong (or linear) leaflets, which join at their baſe, and are hairy. The flowers are produced in ſpikes at the end of the branches, ſtanding round the ſtalk in half whorls; they are of a light blue colour. [Legumes ovate, thick, flatted a little, villoſe, ſwelling where the ſeeds are, in a manner four-celled; partitions cellular-membranaceous, becoming obſolete, or wearing out when ripe. Seeds ſolitary, (two, or ſeldom more in all) large, irregularly round, beaked above the navel by a ſhort knob, flattiſh on both ſides, marked in the middle with a broad ferruginous ſpot[c]. From which circumſtance, I preſume, and not from the corolla, Linnæus derived the trivial name. Linnæus, indeed, ſays the corolla is red, John Bauhin that it is purple, Rivinus that it is blue or red. With us it is blue. Native of the South of France, Spain, Italy and Sicily. It flowers in july, and was cultivated by Gerarde in 1596[d].]

4. This is an annual plant, which riſes with a ſtrong, firm, channelled ſtalk from three to four feet high, covered with a ſoft brownish down, dividing upward into ſeveral ſtrong branches, garniſhed with digitate leaves, compoſed of nine, ten, or eleven wedge-ſhaped hairy leaflets, which are narrow at their baſe where they join the foot-ſtalk, but enlarge upward, and are rounded at the top where they are broadeſt; the foot-ſtalks of the leaves are three or four inches long. The flowers are placed in whorls round the ſtalks above each other, forming a looſe ſpike, which proceeds from the end of the branches. They are large, and of a beautiful blue colour, but have no ſcent. They appear in july, and the ſeeds ripen in autumn. The pods are large, almoſt an inch broad, and three inches long; incloſing three large roundiſh ſeeds, compreſſed on their ſides, very rough, of a purpliſh brown colour.

There is a variety with fleſh-coloured flowers, commonly called Roſe Lupine. It differs only in the colour of the flower, but that difference is permanent. [See the next ſpecies.

In its wild ſtate this plant has quinate leaves, on long petioles; the leaflets are ſpatulate: the flowers blue: the legumes, and the whole plant clothed with long cloſe ferruginous hairs. The flowers are often lateral[e].

The native place of this ſpecies is given very differently; by Linnæus, Arabia, the iſlands of the Archipelago and Spain. Miller ſays it is ſuppoſed to be a native of India. Parkinſon reports, that it is thought to come from beyond Perſia, in Caramania. In the Kew catalogue it is aſſigned to the South of Europe and the Levant. It was cultivated here in 1629[f].

5. This has the ſtature of the preceding. It is a hairy plant. The corollas are pale fleſh-colour, with the middle of the banner red. Leaves lanceolate, bluntiſh[g]. Native of the South of Europe. Cultivated by Mr. Miller in 1731. It flowers in july and auguſt[h].]

6. This has much the appearance of the third ſort, but the ſtalks riſe higher, the leaves have more leaflets, and ſtand upon longer foot-ſtalks; the leaflets are blunt; and the ſeeds are variegated. [According to Linnæus, the leaflets are linear, and the flowers are blue.

Ray deſcribes it as reſembling the third ſort, but more upright, and much taller, being eighteen inches high, and as tall as the white or cultivated Lupine. Leaflets narrow, commonly nine, blunter at the end than in the other ſorts, ſo as to have the appearance of being truncate.—Seeds ovate-globular, equally turgid all round, duſky aſh-coloured variegated with duſky branching ſpots, and whitiſh dots fewer in number; they are ſmooth, and ſmaller than all the reſt. Navel obſolete[i].

Native of Spain and Sicily. Cultivated in 1731, by Mr. Miller[k]. Mr. Ray informs us, that the ſeeds were ſent to him from Cadiz; it is probable, therefore, that he cultivated it before 1686.]

7. Stem a foot high, branching. Leaves digitate, compoſed of ſeven, eight or nine narrow hairy leaflets, near two inches long. Flowers yellow, odorous, in looſe ſpikes at the end of the branches, compoſed of ſeveral (ſix or ſeven) whorls, with ſpaces between them, (and about five flowers in each) terminated by three

[a] Villars. [b] Hort. kew. [c] Hall. 907. [d] Gerarde. [e] Hort. kew. [f] Linn. [g] Hort. kew. from Park. par. [h] Linn. ſyſt. [i] Hort. kew. [k] Gartner. [l] Hort. kew.

or foot flowers, ſitting cloſe at the top; theſe are ſucceeded by ovate ſtatuſh hairy pods, about two inches long, ſtanding erect, and including three, four or five roundiſh ſeeds, a little compreſſed, yellowiſh white, variegated with dark ſpots.

[According to Krocker, the ſtem is upright, from a foot to eighteen inches high. Leaves on very long petioles; (near three inches in length:) leaflets nine, oblanceolate-linear, quite entire, divided by a thick nerve. Lower lip of the calyx trifid, the ſegments linear. Bractes of the whorls ovate, concave, blunt, upright.]

Native of Sicily (and Sileſia) flowering in june and july. [Cultivated by Gerarde in 1596 [1].

8. Stem herbaceous annual roundiſh upright ſtriated two feet high, with aſcending branches. Leaves emarginate ſmooth whitiſh alternate. Flowers yellow, terminating, in ſpikes. Legume oblong turgid bluntly three-cornered tailed ſmooth, containing ſeveral orbicular uncinated ſeeds. Native of Cochinchina and Bengal.

9. Stem ſhrubby, three feet high, with diffuſed branches. Leaves ſmooth, on alternate petioles. Flowers yellow. Native of the eaſtern coaſt of Africa [2].

10. Stem ſimple, a foot high, angular, ſomewhat rugged at the angles. Leaves alternate, crenate-toothed, glaucous beneath, ſomewhat rugged at the nerves, two oppoſite ſubſeſſile, the third petioled; the petiole an inch and half long, blunt beneath, channelled above, running down the ſtem which it marks with grooves. Stipules awl-ſhaped, fixed on each ſide to the baſe of the petiole. Flowers blue, in ſhort axillary ſpikes. Calyx ſhort, ſubvilloſe, hemiſpherical; the upper teeth very ſhort, divaricating, the three lower longer, the middle one more produced. Banner of the corolla ovate plaited: wings ſhorter, concealed within it: keel almoſt equal to it, compreſſed, parted at bottom, with capillary claws. Legume upright, ending in a horned point, one-celled, many-ſeeded, with three grooves at the back. Seeds ſubovate, ſubreniform, a little compreſſed. Native of Mexico. Cultivated in the royal garden at Madrid, before 1791. It flowers there in july [3].]

PROPAGATION AND CULTURE.

Theſe plants are cultivated for ornament in the borders of the flower-garden, where they are ſown in patches with other annuals in the ſpring, where they are to remain; thinning them where they are too cloſe, and keeping them clean from weeds.

To have a ſucceſſion of flowers, the ſeeds may be ſown at different times, viz. in april, may and june, but the ſeeds of thoſe only which are firſt ſown will ripen.

1. The firſt ſort only is perennial. This, however, is propagated by ſeeds as the former, which ſhould be ſown where the plants are to remain; for although the root is perennial, yet it runs ſo deep into the ground that it cannot be taken up entire; and if the root is cut or broken, the plant ſeldom thrives well after. I have traced ſome of the roots of this plant, which have been three feet deep in the ground in one year from ſeed, and ſpread out as far on every ſide, ſo that they muſt have room, therefore the young plants ſhould not be left nearer than three feet aſunder. If this plant is in a light dry ſoil, the roots will continue ſeveral years, and produce many ſpikes of flowers; and although the uſual ſeaſon of flowering is in june and july, yet when rain falls in auguſt, freſh ſtalks ariſe from the roots, which flower at the end of ſeptember, or beginning of october.

2. The ſeeds of the ſecond ſort were formerly uſed in medicine; and are ſometimes eaten in Italy, but they are bitter, and are accounted hard of digeſtion.

This and the ſmall blue Lupine (n. 3.) are frequently ſown in Italy, to manure the ground, eſpecially that which is intended for vineyards. They plough them into the ground as ſoon as they begin to flower.

4. 5. Theſe are generally late in ripening the ſeeds, ſo that unleſs the autumn prove warm and dry, they do not ripen; therefore the beſt way to have good ſeeds, is to ſow them in ſeptember cloſe to a warm wall on dry ground, where they will live through our ordinary winters; and theſe plants will flower early the following ſummer, ſo there will be time for the ſeeds to ripen before the rains fall in the autumn, which frequently cauſes the ſeeds to rot which are not ripe. If a few of the ſeeds of both are ſown in ſmall pots the beginning of ſeptember, and when the froſts begin, the pots are removed into a common hot-bed frame, where they may be protected from hard froſt, but enjoy the free air in mild weather, the plants may be thus ſecured in winter; and in the ſpring they may be ſhaken out of the pots, preſerving the earth to their roots, and planted in a warm border, where they will flower early, and produce very good ſeeds.

All the ſorts of Lupines make a pretty appearance when they are in flower, but the yellow ſort is preferred for its ſweetneſs, though the flowers of this are of ſhort duration, eſpecially in warm weather; therefore the ſeeds ſhould be ſown at ſeveral times, that there may be a ſucceſſion of flowers through the ſeaſon, for they will continue flowering till they are ſtopped by hard froſt; and thoſe which come in the autumn to flower, will continue in beauty a longer time than the early ones. If ſome of the ſeeds are ſown in the autumn on a warm border, the plants will often live through the winter, and flower early in the ſpring.

Calyx inflated, corolla ſhorter than the calyx, flowers hermaphrodite, one or two on the ſtem.

DESCRIPTIONS, &c.

1. [The ſingle Scarlet Lychnis has a perennial root: ſtems three feet high, upright, ſtiff, round, jointed, hairy: at every joint two large leaves of a browniſh green colour: flowers terminating, in a large flat-topped tuft, conſiſting of ſeveral bundles. Corolla of a ſcarlet or bright red orange colour, varying to white, bluſh, and variable, that is, pale red, growing paler till it becomes almoſt white, (var. β.); petals broad at the end and emarginate.—Capſule clothed with the membranaceous calyx, ſtriated with ten villoſe nerves, ovate, narrowing downwards, ſmooth, one-celled, opening into five parts at the top. Receptacle columnar, cylindrical, free, grooved and excavated, naked. Seeds numerous, angular-kidney-ſhaped, rugged with acuminate tubercles in rows, ferruginous [a].

Native of Ruſſia, and Japan. Cultivated in 1596, by Gerarde [b]. In his time it was common in almoſt every garden; but he does not mention any of the varieties. Parkinſon in 1629, and Johnſon in 1633, have the varieties; but the latter ſays, that "the white "and bluſh ſingle and the double one are not to be "found but in the gardens of our prime Floriſts."

Theſe authors call it Flower of Conſtantinople, Campion of Conſtantinople, Flower of Briſtow, and Noon-ſuch; it ſeems to have loſt theſe names, and to be known generally by the name of Scarlet Lychnis. The French call it *Lychnide de Calcedoine, Croix de Jeruſalem* ou *de Malthe*. The Italians alſo name it *Croce de Cavaliere*; the Spaniards *Cruces de Jeruſalem*; and the Portugueze *Cruz de Malta*.]

7. The variety with double flowers is a valuable plant, the flowers are very double, and of a beautiful ſcarlet colour. This has a perennial root, from which ariſe two, three, or four ſtalks, according to the ſtrength of the roots; theſe in rich moiſt land, grow upwards of four feet high; the ſtalks are ſtrong, erect, and hairy. They are garniſhed the whole length with ſpear-ſhaped leaves ſitting cloſe to the ſtalks, placed oppoſite; and juſt above each pair of leaves, there are four ſmaller leaves ſtanding round the ſtalk. The flowers are produced in cloſe cluſters ſitting upon the top of the ſtalk; when the roots are ſtrong, the cluſters of flowers will be very large, and make a fine appearance. They appear the latter end of june, and in moderate ſeaſons continue near a month in beauty. The ſtalks decay in autumn, and new ones ariſe in the ſpring.

2. [Root perennial, browniſh white, ſubacrid. Stems from one to three feet high, upright, ſomewhat angular and grooved, ſwelled at the joints, purpliſh. Linneus remarks, that they are procumbent, and become upright at the time of flowering. Stem-leaves oppoſite, connate, lanceolate, keeled, upright, ſmooth. Peduncles oppoſite, with one generally between them. Calyx ten-angled, of a deep purple colour. Corolla pink or purpliſh red, varying ſometimes to white; the border of the petals dividing into four ſegments, of which the two outer are ſhorter and narrower; the claws have two ſmall ſpear-ſhaped teeth at the top. Capſule one-celled, the mouth having five teeth which turn back. Seeds flattiſh, rugged, of a brown aſh colour [c].

Native of moſt parts of Europe in moiſt meadows: flowering in may and june.

This plant has a variety of names in Engliſh, as Meadow Pink, Wild Williams, Cuckow Flower, Ragged Robin, Crow-flower. Parkinſon calls it feathered wild Campion; Gerarde, Crowe flowers, wilde Williams, marſh Gilloflowers, and Cockowe Gilloflowers; Ray, Meadow Campion; to Mr. Curtis Meadow Lychnis ſeems moſt eligible. Several plants have the name of Cuckow-flower from their appearing about the ſame time with that bird. Gerarde ſays the true Cuckow-flower is *Cardamine pratenſis*. Shakſpeare's Cuckow-buds are of yellow hue, and probably *Ranunculus* or Crowfoot. Orchis, Arum and Oxalis or Wood-ſorrel are all called by ſome after the Cuckow. Goats, ſheep and horſes are ſaid to eat it; but it ſeems generally agreed that none of our domeſticated quadrupeds are fond of it. The beauty of the flowers entitles it to a place in the gardens of the curious [d].]

7. The variety with double flowers is frequently cultivated in flower-gardens for ornament. It only differs from the ſingle in the multiplicity of the petals, and is commonly known by the title of Double Ragged Robin. [Some call it, ſays Parkinſon, the Fair Maide of France. It is ſometimes found wild in England, as near Bungay in Suffolk by Mr. Woodward.

3. Root perennial. Stems a ſpan high, upright, ſmooth. Leaves linear-lanceolate, ſmooth. Flowers in a dichotomous panicle. Calyx ſmooth, with blunt teeth. Petals white, the length of the calyx. Styles four or five. Capſule longer than the calyx [e]. Native of Switzerland and Auſtria.

4. Stems a ſpan high, with the upper joints viſcid. Leaves lanceolate, an inch long. Calyx viſcid, three lines long, with headed villoſe hairs on it, ten-ſtreaked, bluntly toothed. Petals white, emarginate, with a tooth on each ſide above the middle, border four-lobed, ſpreading, the middle lobes larger and rounded, the lateral ones acute; ſegments of the earlets blunt, ovate. Germ on a columnar receptacle. Capſule one-celled, ſix-valved, with a linear receptacle. Seeds compreſſed, kidney-ſhaped (10 fifty) ruſtous, with the edges lacerate-ciliate. Styles four or five [f], very ſeldom three. Native of Auſtria.

5. The whole plant is ſmooth. Stem ſimple round upright, a foot high. Leaves oppoſite, embracing, oblong-ovate, acute, entire, an inch or a little more in length. Flowers aggregate, about three, ſeſſile. Calyx ten-angled. Petals gaſhed, crenate-multifid. Filaments the length of the tube of the coroila, filiform. Germ ſuperior. Styles five, much ſhorter than the tube of the corolla [g]. Native of China and Japan. Introduced in 1774, by John Fothergill, M.D. It flowers in june and july [h].]

6. This has long, narrow, graſs-like leaves, which come out from the root without order, ſitting cloſe to the ground; between theſe come up ſtraight ſingle ſtalks, which in good ground riſe a foot and half high; at each joint of the ſtalk come out two leaves oppoſite, of the ſame form as the lower, but decreaſing in their ſize upwards; under each pair of leaves, for an inch in length, there ſweats out of the ſtalk a glutinous liquor, which is almoſt as clammy as birdlime, ſo that ants and other inſects which happen to light upon theſe places, or attempt to creep up to the flowers, are faſtened to the ſtalk, whence this plant has the title of Catchfly. The ſtalk is terminated by a cluſter of purple flowers, and from the two upper joints come out on each ſide of the ſtalk a cluſter of the ſame flowers, ſo that the whole forms a ſort of looſe ſpike. Theſe appear in the beginning of may, and the ſingle flowers are ſucceeded by roundiſh ſeed-veſſels, which are full of ſmall angular ſeeds ripening in july.

[Root perennial, yellowiſh on the outſide, white within. Stem round not grooved, ſmooth. Leaves connate, upright, ciliate at the baſe, lanceolate-acuminate, quite entire, with a red tip, three inches long, three lines wide, bright green, ſmooth. Flowers terminating in cloſe whorls all together forming a ſpike; others come out from the axils on long pedincles. Very ſmall lanceolate red bractes ſeparate the flowers; which are ſeven lines or ſomewhat more in diameter. Calyx purple, ſwelling, viſcid, with ten red ſtreaks. Petals entire, ſometimes ſlightly waved about the edge and emarginate at the top, bright red-purple, with white claws, almoſt half an inch long, and three lines wide, having two appendicles at the throat. Capſule conical, five-celled. Seeds kidney-ſhaped, rugged.—It varies with white flowers; and is ſold in foreign countries for Centaurium minus [i].

Native of moſt parts of Europe, in dry and mountainous paſtures, eſpecially among buſhes. In Britain it is rare. Lhwyd and Tancred Robinſon found it in Wales. Thomas Willifell upon the rocks in Edinburg Park. And Mr. Crowe near Croyden, in Surrey. It

[a] Curtis. [b] Lion. ſuppl. [c] Scopoli.
[d] Thunberg. [e] Hort. kew.
[f] Pollich. Krocker. Haller.

flowers in may and june. In Engliſh it is named, narrow-leaved Catchfly or Limewort, Red German Catchfly, Catchfly Cuckow-flower, and Viſcous Lychnis.

7. Root perennial. Root-leaves in a tuft, linear, ſlightly keeled, acute, ſmooth, thickiſh, ſomewhat channelled, ſubciliate at the baſe. Stem a finger, half a foot or a ſpan in height, ſimple, round, upright, having four or five joints flatted a little at top. Stem-leaves narrow, pointed, upright, ſomewhat rugged; the uppermoſt membranaceous. Flowers collected into a thyrſe or corymb, on three-flowered very ſhort peduncles. Bractes between the flowers ſubdiſphanous. Calyx pale, with blunt concave claws. Petals purple, cloven half way, ſharp, without any crown. Anthers red. Germ roundiſh. Styles four or five. It reſembles the preceding ſpecies very much, but is not viſcous[a]. It is only half the ſize; the petals are not entire, but cloven. The piſtils, which are often ſix and even more, are ſhorter than the petals before the flowers open, but during the time of flowering lengthen gradually till they become longer than the petals[b].

Native of the Alps in Europe, and Siberia. Cultivated in 1768 (1759) by Mr. Miller. It flowers in april and may[c].] Mr. Miller ſays the beginning of june, and that the ſeeds ripen in auguſt.

[In the Kew catalogue it is marked as biennial. Allione ſays it is perennial: that the calyx is inflated; petals deeply cut, with the coronal ſcales linear: ſtyles five, longer than the flower.

8. This is an annual plant, native of Portugal. Introduced in 1778, by Edward Gray, M.D. It flowers in july[d].]

9. Root perennial, from which ariſe many narrow leaves ſitting cloſe to the ground. Stalks a foot high, dividing into branches by pairs. Flowers from the diviſion of the branches, and at the top of the ſtalks. Petals white. Capſules roundiſh. Seeds ſmall, angular.

[This has the ſtature of S. rupeſtris, but the root is perennial, the leaves are leſs ſmooth, and the five ſtyles diſtinguiſh the plant. Native of Siberia[e]. Cultivated by Mr. Miller in 1759.

10. Root perennial, the thickneſs of the little finger, white, of a ſlightly acrid and bitter taſte, furniſhed with numerous fibres. Stalks ſeveral, upright, from one to three feet high, round, hirſute, jointed, purple; the joints ſwelled, the uppermoſt branches forked. Leaves oppoſite, connate, ovate-acuminate, hirſute, ſlightly nerved. Calyx hairy, ſtriated, purple, five-toothed; in the female more turgid. Petals purple, obcordate: at the bottom of the lamina or broad ſpreading part are two or four ſmall upright white blunt appendicles. Germ ovate, ſurrounded by a nectary at the baſe. Capſule one-celled, with ten teeth at the mouth. Seeds gray, ſomewhat rugged.

Native of many parts of Europe, in moiſt ſhady ditches, by the ſides of hedges, and ſometimes in woods, flowering in may and june[f].

Johnſon in Gerarde calls this plant Red or Roſe wild Campion; Parkinſon, Red Wild Campion; and Ray, Red-flowered Wild Campion.]

β. A variety of this with double flowers is cultivated in gardens by the name of Red Batchelor's Buttons. It is an ornamental plant, and continues long in flower.

11. The White Wild Campion was regarded as a diſtinct ſpecies from the preceding or Red by all the old Botaniſts. Linnæus ſuppoſed them to be only varieties, and he has been followed by moſt modern botaniſts; by ſeveral however with marks of doubt. I am not for multiplying ſpecies; and the leſs ſo, becauſe this rage which prevailed ſo much at the beginning of this century, ſeems to be recurring at the end of it. In this caſe however I muſt own it was always my opinion that the Red and White Lychnis differed ſpecifically. I had indeed almoſt given up my opinion to Linnæus's ſuperior authority and judgement; but finding on examination that I am ſupported by ſeveral good judges, I have ventured to ſeparate them.

The two plants agree in moſt points of the above deſcription, they certainly correſpond in ſtructure, both have male and female flowers on ſeparate roots, and both are ſometimes found with hermaphrodite flowers[g]. There are many circumſtances however in which they differ, whether ſufficiently or not to conſtitute different ſpecies, let others determine from more accurate examination or from culture.

Mr. Miller, who regards them as diſtinct ſpecies, informs us that the ſtalks of this are branched out much more than in the Red, the leaves are longer and more veined, the flowers ſtand ſingly upon pretty long peduncles, and are not produced in cluſters as in the Red, it is very hairy, the calyx is more ſwollen, and it flowers a month after the Red.

Ray obſerves, that in the Red the ſtems are weaker and more flaccid than in the White.

Dr. Withering remarks, that in the White the petals on the male plant have the lamina divided down to the claws, but in the female they are only cloven half way down. Whether this may be the caſe in the Red, I have not an opportunity of obſerving, that not growing in the country where I now am, and authors not having remarked the circumſtance.

Allione follows Linnæus, Haller, Scopoli, &c. in not ſeparating this from the preceding. He thinks however that they are ſpecifically different, becauſe he obſerves that the Red grows only in mountainous and watery places, and that it is not ſo much branched and ceſpitoſe as the White.

Krocker reports, that in Sileſia the plant with white flowers is entirely different from that which has red: the ſtem being higher, more diffuſed, ſuberect; the leaves longer but narrower, leſs hirſute, with whitiſh veins; the joints of the ſtalk bigger; calyxes in the male cylindrical, in the female ventricoſe, in both longer than in the Red, whitiſh, with ten green veins; the claws of the petals longer, the petals themſelves white, with white appendicles or earlets; anthers aſh-coloured; ſtyles white: this is common in fields &c., that only on mountains.

But the late lamented Dr. John Sibthorp is the firſt among the moderns who has dared to give them as diſtinct ſpecies; having remarked that in the Red Lychnis the capſules are roundiſh, and that its ſcentleſs flowers ſtand open through the day; whereas the White has conical capſules, and its odoriferous flowers open only towards evening. Hence his ſpecific characters, and elegant trivial names: both which I have adopted.

The colour, with other circumſtances relative to the two plants, led Mr. Curtis to ſuſpect that they are not varieties but diſtinct ſpecies, and he remarks that cultivation and farther attention to them will probably enable him to ſpeak of this with more certainty. Mr. Robſon, having cultivated both, he is ſatisfied they are diſtinct ſpecies, though both liable to change the colour of their flowers to fleſh-colour[h].

To all this we may add that the Red and White affect different ſituations, and are never found promiſcuouſly. The White is frequent in fallow fields, ſometimes ſo plentifully as to make them appear at a diſtance quite white; but the Red is never found there. The White ſeems to prefer dry ſoils, and the Red moiſt ones. The former is very common in Sweden, not ſo the latter. No one ever ſaw the Red Campion in the County of Cambridge, though the White is common there, and the Red no leſs common in ſome of the neighbouring counties. Mr. Lightfoot ſays, the rocks in the iſland of Ailſa are covered with the red-flowered only. According to Kroecker, the White is very common in Sileſia on the borders of fields, but the Red is found only in the mountainous parts. So alſo ſays Allione, that the Red occurs in wet ſhady places and ſprings at the foot of the Alps; but that the White is every where common in the plains by hedges, ditches and highways. And Pollich, that the White is every where on banks, among buſhes, by walls

[a] Linn. ſuec. & ſyſt. [b] Villars. [c] Hort. kew.
[d] Ibid. [e] Linn. ſpec. [f] Curtis.
[g] Withering. [h] Ibid.

walls and among rubbiſh; the Red in woods and hedges. And Villars, that the Red occurs on the Alps and mountains by the ſides of ſtreams; differing from the White not only in colour and place, but in having the upper leaves coloured, and the calyx villoſe without any diſtinct veins. The White is found in ſtony places, by way ſides, in low ſituations; its calyx is thicker, harder, almoſt cartilaginous, covered with veins forming a kind of net.

There are ſeveral varieties of the White Campion. 1. With purple or bluiſh-coloured flowers. Mr. John Templeton of Orange Grove near Belfaſt informs me, that a White female Campion brought into his garden, having red males not far diſtant, but no white ones, produced offspring with bluiſh-coloured flowers.—2. With quadrifid petals[1].—3. With hermaphrodite flowers. Both red and white indeed are ſubject ſometimes to this variation. Many authors mention it, but it does not ſeem to occur very frequently. Linnæus ſays, *varias hermaphr. edidit*: I found it only once, namely on the ſixth of June 1765, near Cambridge, among other plants which had male and female flowers diſtinct. The germ was of the uſual ſize, full of ſeeds; the piſtils were very ſhort, the anthers four times as large as in the common male flowers, with the pollen of a duſky purple colour. Though I had not the good fortune to exhibit the monſter, as Linnæus did in the year 1752, to above an hundred pupils, *ne de exiſtentia ejus quis dubitet*, yet I ſhall hope to meet with the credit of the candid, though Leers ſays that he never had the good fortune to ſee it.]—4. With double flowers, cultivated in gardens by the name of Double White Batchelor's Buttons. An ornamental plant in the flower-garden, though it does not make ſo good an appearance as the Double Red.

12. [Root fibrous. Stem ſingle, upright, a ſpan high, entire, having three or four joints, ſcarce apparently rugged. Leaves oppoſite, linear-lanceolate, the upper ones ſhorter and narrower; at the root are four leaves, from two neighbouring joints. A ſingle flower terminates the ſtem, nodding horizontally. Calyx ovate, inflated, with ten brown hiſpid raiſed lines, and a five-toothed blunt mouth, almoſt cloſed. Petals oblong; claws three-cornered flat, upright; border ſcarcely any, emarginate, duſky, ſhorter by half than the calyx. Stamens ſhorter than the calyx, but rather longer than the corolla. Germ oblong. Styles five, a little longer than the ſtamens, but ſhorter than the calyx. Capſule cylindrical, oblong, a little attenuated in the middle, blunt, concealed within the calyx, one-celled[2].

Although it be very diſtinct and conſtant, with hermaphrodite flowers, yet there is no doubt but that it owes its origin to L. dioica[3].

Native of the mountains of Lapland and Siberia. In the latter it occurs with ſeveral flowers on the ſtem[4]. Cultivated by Mr. Miller in 1759.]

Mr. Miller has another ſort, which he calls L. luſitanica, it having been introduced from Portugal by John Browning, Eſq. of Cheſſea, Maſter in Chancery, a great cultivator of exotic plants, before 1759. He thinks it probably a variety of one with ſingle flowers that is wild in that country, and that it approaches neareſt to the Double Ragged Robin. It is perennial, with many oblong narrow leaves ſitting cloſe to the ground. It divides into ſeparate heads, like L. Viſcaria, and from each of theſe comes out an upright ſtalk nine inches high, dividing at top by pairs, and from the middle of each diviſion comes out a ſlender pedunclе two inches long, with one double purple flower at the top, the petals of which are much jagged, and the calyx marked with deep purple ſtripes; there are other pedunclеs from the axils, ſuſtaining one or two flowers.—May not this be a variety of L. Leea, n. 8.

PROPAGATION AND CULTURE.

1. Single Scarlet Lychnis is eaſily propagated by ſeeds, which ſhould be ſown on a border expoſed to the eaſt, in the middle of march. The plants will appear in april, when if the ſeaſon is dry, they ſhould be refreſhed with water two or three times a week. By the beginning of june the plants will be fit to remove, when there ſhould be a bed of common earth prepared to receive them; into which they ſhould be planted at about four inches apart, obſerving to water and ſhade them till they have taken root; after which time they will require no other care but to keep them clean from weeds till the following autumn, when they ſhould be tranſplanted into the borders of the pleaſure-garden, where they are to continue. The ſummer following theſe plants will flower and produce ripe ſeeds, but the roots will abide ſeveral years, and continue to flower. This ſort flowers in june and july, and the ſeeds ripen in autumn. It may alſo be propagated by off-ſets, but as the ſeeds ripen ſo freely, few perſons trouble themſelves to propagate the plants any other way.

2. Double Scarlet Lychnis is propagated by ſlips taken from the roots in autumn; but as this is a ſlow method of increaſing the plants, the beſt way to have them in plenty, is to cut off the flower-ſtalks in june before the flowers appear, which may be cut into ſmall lengths, each of which ſhould have three or four joints, which ſhould be planted on an eaſt border of ſoft loamy earth, putting three of the joints into the ground, leaving one eye juſt level with the ſurface; theſe muſt be watered, and then covered cloſe with bell or hand-glaſſes, ſo as to exclude the outward air, and ſhaded with mats when the ſun ſhines hot upon them. The cuttings ſo managed will put out roots in five or ſix weeks, when they muſt be expoſed to the open air, and in very dry weather they ſhould be now and then refreſhed with water, but it muſt not be repeated too often, nor given in large quantities, for too much moiſture will cauſe them to rot. Theſe will make good plants by the following autumn, when they may be tranſplanted into the borders of the pleaſure-garden, where they will flower the following ſummer.

Some people who are covetous to have their plants flower, ſuffer the ſtalks to remain till the flowers are decayed, and then cut them off to plant; but by that time the ſtalks are grown hard, ſo but few of them ſucceed, and thoſe which do, will not be near ſo good plants as thoſe which are planted earlier; therefore it will be better to ſacrifice the flowers of ſome roots for this purpoſe. Theſe plants delight in a ſoft, rich, loamy ſoil, not too moiſt or ſtiff, in which they will thrive and flower very ſtrong, but they do not care for much dung, which very often cauſes the roots to canker and rot, ſo that in the rich dunged lands about London, they do not thrive well. As theſe plants grow tall, they ſhould be planted in the middle of large borders, and not crowded with other plants, for their roots extend to a large diſtance, ſo if they are incommoded by other roots, it will ſtint their growth.

I have not ſeen any double flowers of the two other varieties, but have been informed that there are of both the white and the fleſh-colour with double flowers in ſome of the French gardens. Theſe make a variety, but are not ſo beautiful as the ſcarlet, ſo are not much eſteemed.

2. The ſingle Meadow Lychnis is not kept in gardens, though by no means deſtitute of beauty; but the variety with very double flowers is propagated for ornament. It is commonly known by the name of Double Ragged Robin, and is increaſed by ſlipping the roots in ſeptember.

6. Viſcous Lychnis or Red German Catchfly was formerly cultivated in flower-gardens, but ſince the variety with double flowers has been produced, the ſingle one has been neglected. It may however be propagated in plenty by parting the roots in autumn, at which time every ſlip will grow; or if the ſeeds are ſown in the ſame manner as is directed for the firſt ſort, the plants with ſingle flowers may be raiſed in plenty. This delights in a light moiſt ſoil and a ſhady ſituation.

β. The double flowering has not been known forty years in the Engliſh gardens, but it is now ſo common as to have excluded that with ſingle flowers; it differs only from that in the doubleneſs of the flowers. As this never produces ſeeds, it can only be propagated by parting and ſlipping the roots; the beſt time for this

[1] Leers. [2] Linn. Supp. [3] Linn. Syſt. [4] Linn. Spec.

this is in autumn, at which time every flip will grow. If this be performed in September, the flips will have taken good root before the froft, and will flower well the following fummer; but if they are expected to flower ſtrong, the roots muſt not be divided into ſmall flips, though for multiplying the plants, it matters not how ſmall the flips are. Theſe ſhould be planted on a border expoſed to the morning ſun, and ſhaded when the ſun is warm till they have taken root. If the flips are planted in the beginning of September, they will be rooted ſtrong enough to plant in the borders of the flower-garden by the middle or latter end of October. The roots of this multiply ſo faſt, as to make it neceſſary to tranſplant and part them every year; for when they are let remain longer, they are very apt to rot. This requires the ſame ſoil and ſituation as the ſingle.

7, 8. Theſe are propagated by ſeeds, and alſo by parting the roots. They muſt have a moiſt ſoil and ſhady ſituation. The roots may be parted, and the plants removed in autumn. The ſeeds may be ſown upon a ſhady border in march, keeping the ground moiſt in dry weather. When the plants are of a ſize to remove, tranſplant them into a ſhady border, where they may remain to flower.

10, 11. The double varieties of Red and White Wild Campions, commonly called Red and White Batchelor's Buttons, are ornamental plants, and conſtitute long in flower. They are propagated by flips, planted the beginning of auguſt in a ſhady border of loamy earth, where they will take root in ſix weeks or two months, and may then be tranſplanted into the borders of the flower-garden. Theſe roots ſhould be annually removed, otherwiſe they frequently rot: and young plants muſt be propagated by flips to ſupply the decay of the old roots, which are not of very long duration. The Red thrives beſt in a ſoft loamy ſoil, and in a ſhady ſituation, where it has only the morning ſun.

The Double White Batchelor's Button does not make ſo good an appearance as the Red. This will thrive in a drier ſoil, and a more open expoſture.

Portugal Lychnis is increaſed by flips, in the ſame manner as theſe, but coming from a warm country, it is impatient of cold, and will not live through the winter in an open border, nor does it thrive well in a pot. It ſucceeds beſt when planted cloſe to a ſouth wall in dry unhunged earth, or brick rubbiſh; for in rich or moiſt ground the roots peciently rot, as they do alſo when they are watered.

DESCRIPTIONS, *&c.*

1. This ſhrub is ſcarcely a fathom in height, very much branched, upright. Branches and branchlets ſcattered, round, ſlender or filiform, aſh-coloured, ſmooth, ſpreading, drooping at top. Leaves oppoſite, ſubſeſſile, attenuated below, blunt with a point, quite entire, ſmooth, ſpreading, dark green above, half an inch long: there are cluſters of many ſmaller leaves in the axils. Flowers on the branchlets from a cluſter of leaves, ſeſſile, upright, ſolitary or aggregate, deciduous. Calyx much ſhorter than the corolla, ſmooth, five-toothed. Tube of the corolla greeniſh-white, a line in length: ſegments of the border ovate, pale fleſh-colour, a little ſhorter than the tube; the opening of which is cloſed with villoſe hairs. Filaments faſtened to the tube longitudinally below the opening. Anthers oblong, ſtanding a little, white. Germ ſuperior. Style capillary, white, the length of the corolla. Stigmas two, ſeldom three, oblong, whitiſh, villoſe. It varies with double flowers [a].

It occurs twice in Syſt. veget. In the Supplement it was named fœtidum. Kæmpfer and Koenig having reported that the bruiſed leaves ſmell like dung; which is not true of this ſhrub, but of a tree called by the Dutch *Struntboat* [b].

It is deſcribed by Retzius from Koenig's ſpecimens. It is made a diſtinct genus under the name of Seriſſa, by L'Heritier called Buchozia, and by Loureiro Dyſoda.

Native of Japan; Thouin found it in China, and Koenig in Madeira [c]. Introduced in 1787, by Monſ. Cels. It flowers here moſt part of the Summer [d]. In Japan, from april to november. This ſmall handſome ſhrub is planted frequently for hedges in Japan [e].

2. Native of the Cape of Good Hope, where it was found by Thunberg. This ſtands in the Supplement under the name of L. inerme. Mr. Miller has one (n. 9.) with the ſame name; but his is a Chineſe plant.

3. This riſes with irregular ſhrubby ſtalks ten or twelve feet high, ſending out ſeveral crooked knotty branches, covered with a whitiſh bark, and armed with long ſharp ſpines, upon which grow many cluſters of narrow leaves; theſe thorns often put out one or two ſmaller on their ſides, which have ſome cluſters of ſmaller leaves upon them; the branches are garniſhed with very narrow leaves an inch and a half long, and at the baſe of theſe come out cluſters of ſhorter and narrower leaves. The flowers come out from the ſide of the branches, ſtanding upon ſhort foot-ſtalks; they are of a dull purple colour. The berry is of a yelloweiſh colour when ripe, incloſing ſeveral hard ſeeds. This uſually flowers in june and july, and the ſeeds ripen in the autumn; but frequently a few flowers come out in all the ſummer months.

[Stem ſtraight, rigid. Flowers very dark purple. Berries globular, very dark red [f].

Native of the Cape of Good Hope, where ſheep feed on it.—Cultivated in 1714, by the Dutcheſs of Beaufort [g].]

[a] Thunberg. [b] Retzius. faſc. 2. [c] Linn. ſuppl. [d] Hort. kew. [e] Thunberg. [f] Linn. [g] Hort. kew.

6. This has many irregular ſhrubby ſtalks, which riſe eight or nine feet high, ſending out ſeveral irregular branches, covered with a white bark, and armed with pretty ſtrong thorns; the leaves are narrow at bottom, growing broader upward, and are of a pale green colour. The flowers come out from the ſide of the branches; they are of a purpliſh white colour and ſmall, and make no great appearance. This ſort flowers in june and july, but rarely produces any ſeeds in this country. The leaves remain till winter, when they fall off.

It is a native of the South of France, Spain and Italy, in hedges.

[4. This is a ſhrub of about ſix feet high, if meaſured to the tips of the pendent branches: the ſtems are many, branching almoſt immediately from the root; branches long, dependent, or procumbent, unleſs ſupported; of the thickneſs of a tobacco-pipe, round, ſpinoſe, leafleſs; decompoſed from about the middle, where they ſhoot into ſmaller branchlets, which are ſpiny, very ſpreading, and leafy towards their tips. Leaves faſciculated, growing by fives and ſometimes by nines, or more, juicy, linear, glauceſcent, obtuſe at margin and tip, attenuated towards the baſe. Flowers two or four together, outwardly pale, and of a greenith-purple; within purple, with a pale throat, marked by fifteen deeper ſtreaks; ſtamens longer than the corolla; anthers ſulphur-colour, oblong, incumbent.

5. This reſembles L. afrum very much, inſomuch that it may be doubted whether its fleſhineſs and the prevalence of the number four in the fructification, make it a diſtinct ſpecies. Found at the Cape of Good Hope by Thunberg [h].

6. Stem upright, round, branched, full of chinks aſh-coloured. Branches alternate, ſpreading, ſmooth. Spines axillary, ſolitary, ſpreading very much, awl-ſhaped, ſhorter than the petiole. Leaves alternate, ſpreading, from twelve to twenty lines long, from eight to fifteen lines wide. Petioles one third of the length of the leaves, ſpreading very much, round, pale purple. Panicle leafy, from the end of the ſhoots, racemed at top. Flowers peduncled, upright, white. Bractæ ſmall, linear, acute, under each pedunele. Corolla blue, ſmelling very ſweet: tube ſtraight, longer than the calyx; ſegments of the border ovate, ſharpiſh, ſpreading or reflex. Filaments upright, longer than the corolla, inſerted at the baſe of the tube, cloſing the tube with a villoſe beard. Anthers roundiſh, acuminate, two-celled, peltate, white. Germ ſuperior, ovate, with a conical tip, and a tubercle on each ſide of the baſe. Style the length of the ſtamens. Stigma varying; headed, or oblong ſubbivalve, or bifid acute ſubreflex, green. Berry placed on the calyx, globular, fleſhy, two-celled, two-ſeeded, yellow. Seeds ſolitary, bony, three-toothed at the baſe, gibbous on one ſide, ſtartiſh on the other, two-celled. It has the flowers of Lycium, with bearded ſtamens; but the fruit of Ehretia, with bony, three-toothed, two-celled ſeeds, but only two in number. It varies with waved leaves.

Native of Peru, where it was found by Dombey, Joſ. Juſſieu introduced it many years ſince into the Paris garden, where it flowers in ſummer and autumn, but ſeldom produces berries [i]. Introduced here in 1780, by Monſ. Thouin [k].

7. This is a weak ſhrub, nodding and decumbent unleſs ſupported. Bark of the branches whitiſh. Flowers from each bud from two to five, each on its proper pedunele. It differs from all the other ſorts, in having the mouth of the calyx two-lobed, or ſometimes three-lobed. Border of the corolla ſpreading, with the throat pale ſtreaked with black, and purple or pale red within. Four ſtamens the length of the whole corolla, the fifth ſhorter. Berries ovate, yellow [l], or vermilion red, fleſhy, with a longitudinal depreſſed ſtreak on each ſide, ſmooth, ſhining, two-celled: partition fleſhy, narrow, correſponding with the outer groove. Receptacle ovate-globular, fleſhy,

[h] Linn. ſuppl. [i] L'Heritier. [k] Hort. kew. [l] Linn. ſpec. and mant.

excavated, red, intimately connate with the partition. Seeds about twelve in each cell, roundish, compressed, with small raised dots on them, whitish [a].

Native of Europe, Asia and the Cape of Good Hope. Cultivated in 1759, by the Dutchess of Beaufort. It flowers from may to october [b].

1. barbarum (n. 4.) of Miller is that which was brought from Africa by Dr. Shaw. It has a shrubby stalk seven or eight feet high, sending out several irregular branches, armed with strong spines, and furnished with short thick leaves. The flowers, which come out from the side of the branches, are small and white. They appear in july and auguſt but do not produce seeds in England.

1. halimifolium (n. 6.) of Miller, to which he attributes the synonym of Duhamel, here given under the Chinese variety, is given by Reichard as a synonym to L. barbarum. Miller says, it is a native of China, whence the seeds were brought to the Paris garden, and thence sent to him by Bernard de Jussieu.—The stalk is four or five feet high, sending out many irregular branches, covered with a very white bark, and armed with a few short spines. Leaves about three inches long, and one inch broad in the middle, alternate, pale green. The flowers appear in june and july, and are succeeded by small round berries that ripen in the autumn, when they are as red as coral.

3. L. chinense (n. 5.) of Miller rises with weak irregular diffused branches to a great height; requiring support: some of these branches have in one year been upwards of twelve feet long. The lower leaves are more than four inches long, and three broad in the middle; they are of a light green and a thin consistence, placed without order on every side the branches. As the shoots advance in length, the leaves diminish in size, and towards the upper part they are not more than an inch long, and a quarter of an inch broad; they sit close to the stalks on every side. The flowers come out singly at every joint towards the upper part of the branches, on short slender peduncles: they are of a pale colour with short tubes; the brims are spread open broader than either of the former sorts, and the style is considerably longer than the tube of the corolla.

It flowers in auguſt, september and october, and retains its leaves till november. It is a native of China, whence the seeds were brought to England a few years before (1759), and being raised in several gardens, by some were thought to be the Thea.

[Loureiro, who observed it about Canton, describes it to be four feet high, cryptotle, upright, with rising branches, and straight solitary scattered prickles. Leaves lanceolate, quite entire, smooth, in clusters or scattered. Flowers purple, solitary, axillary, on a long reflex peduncle. Calyx upright, trifid with one segment two-toothed. Stamens as long as the corolla, closing the throat with a dense beard. Berry small, red, ovate, two-celled, containing many seeds.—The Chinese use a decoction in wine, or an infusion in water, of the berries as a tonic, analeptic and cephalic.]

4. This differs from L. barbarum in being able to stand upright without affiſtance; in having the leaves, though lanceolate as in that, not flat but oblique or flexuose; the branchlets flexuose, not rendered angular by a line running down from the petiole; the surface not smooth but subtomentose; and finally, spines from every bud. It differs from L. afrum in having lanceolate leaves, and round flexuose branchlets.

Native of the South of Europe [c]: as Spain, Portugal and the South of France, observed by Clusius; and by Ray about Montpelier and Florence, flowering both in march and autumn. Clusius says they eat the tender shoots in Spain, with oil and vinegar: and Micheli, that it is used for hedges in Tuscany, where they call it *Spina da serare di crocifiſſi*; supposing it, in common with several other prickly shrubs, to be that which afforded the crown of thorns to our Saviour before his crucifixion.—It was introduced in 1780, by Peter Simon Pallas, M. D.[d]

9. This is an elegant shrub, on account of the whiteneſs of the branches, rods or twigs, which are many, a foot or eighteen inches long or more, branched, ascending. Spines alternate, awl-shaped, rigid, spreading, white or yellowish, surrounded with leaves and flowers at the base. Leaves sessile, fleshy, blunt. Flowers from the upper part of the twigs among the leaves, two or three to each spine, on short peduncles. Calyx bell-shaped, widish, subbilabiate, the upper lip trifid, the lower bifid. Tube of the corolla white, a little crooked at top, spreading out into a purple border with blunt segments: anthers simple, incumbent. Style inflex at top, with a simple stigma. It varies with four and six stamens, and the same number of segments in the corolla. Berries the size of a Currant, black and succulent. Seeds most frequently ten, kidney-form. It differs from L. europæum, to which it bears great affinity, in size, and both the colour and form of the flower.

Native of Tartary about the Volga; in the deſerts of Turcomannia and Hyrcania, especially in sandy soils replete with nitre. When out of flower it bears great resemblance to Nitraria, except that it is more thorny. Gmelin observed a dwarf and very thorny variety in the sands near the Caspian sea [e]. Is not this the species said in the Kew catalogue to have been introduced by Pallas; the learned professor having, as he informs us, taken it originally to be L. europæum?

10. This is said by Linnæus to be a native of Mexico, on the authority of Miller: but we do not find it among his species.

Miller has set down ten species, which we are at a loss to make out satisfactorily. The first, third and eighth seem to be the *afrum*. The fourth, fifth and sixth belong to *barbarum*. The second and seventh are inhabitants of the Cape, and may be the *afrum* or varieties of it: but why the second should have the name of *italicum* I am at a loss to imagine.] L. inerme (n. 9.) was raised by him from Chinese seeds, and was for many years taken for the Tea-tree, till it produced flowers. It rises with a strong woody stalk six or seven feet high, sending out many smooth branches, covered with a brown bark, and having no thorns. Leaves lanceolate, three inches long, and near three quarters of an inch broad, alternate, on short petioles; they are of a deep green, and continue all the year. The flowers are white, and have not been followed by seeds. [May not this be the same with the cochinchinense of Loureiro? L. cordatum (n. 10.) is Arduina bispinosa.

11, 12. Natives of the Cape of Good Hope [f].

13. This shrub is four feet high, almost upright, branched. Flowers white, in pedimcled cymes. Border of the corolla reflex. Stamens nearly equal to the corolla, with many hairs filling up the tube of the corolla. Berry roundish, two-celled.

Native of Cochinchina, in woods [g].]

PROPAGATION AND CULTURE.

1. 2. 3. 5. 6. 11. 12. These plants may be increased by seeds, cuttings or layers. If by seeds, they should be sown in the autumn soon after they are ripe; for if they are kept out of the ground till spring, they seldom come up the first year. If the seeds are sown in pots, the pots should be plunged into some old tan in the winter, and in very severe frost covered with Peas-haulm or straw, but in mild weather should be open to receive the wet; in the spring the pots should be plunged into a moderate hot-bed, which will soon bring up the plants; these must be inured to bear the open air as soon as the danger of frost is over, and when they are three inches high, they may be shaken out of the pots, and each planted in a small separate pot, filled with loamy earth, and placed in the shade till they have taken new root, when they may be removed to a sheltered situation, where they may remain till the autumn; then they should be either removed into the green-house, or placed under a hot-bed frame

[a] Gærtner. [b] Hort. kew. [c] Linn. mant. [d] Hort. kew. [e] Pallas. [f] Thunberg. [g] Loureiro.

to shelter them from hard froft; for thefe plants being too tender to live in the open air in England, they muft be kept in pots and treated in the fame way as Myrtles, and other hardy green-houfe plants; but when the plants are grown ftrong, there may be a few of them planted in the full ground in a warm fituation, where they will live in moderate winters, but in hard frofts they are commonly deftroyed. If the cuttings of thefe plants are planted in a fhady border in July, and duly watered, they will take root, and may then be treated in the fame way as the feedling plants.

This is the common mode of increafing them, for fome never produce feeds in England.

4. 8. 9. Are hardy plants, and may be increafed by cuttings or layers.

7. Is alfo increafed by cuttings, planted in the fpring, before they begin to fhoot, in a border expofed to the morning fun. Thefe fhould not be removed till the autumn, when they may be planted to cover walls, for the branches are too weak to fupport themfelves.

β. Increafes faft by its creeping roots; and the cuttings will take root as freely as Willows.

Several of thefe fhrubs from China and the Cape will bear the open air in a warm fituation and dry foil, when they have once acquired ftrength; except in very fevere winters: efpecially if the roots be covered with litter, and the branches with mats.

LYCOPERDOIDES. }

LYCOPERDON. (*So named by Tournefort, from λυκος, lupus, & περδω, pedo, q. lupi crepitum dicentes.*)

Lin. gen. n. 1217. *Reich. n.* 1333. *Schreb. n.* 1683. *Tournef. t.* 331. *Mich. t.* 97. *Vaill. bot. par.* 16. 4.—10. Boviſta. *Dill.* Lycoperdoides. *Mich. t.* 98. Lycoperdaſtrum. *Mich. t.* 99. Geaſter. *Mich. t.* 100. Carpobolus. *Mich. t.* 101.

Claſſ. 24. 6. Cryptogamia Fungi.
Nat. order of *Fungi* or *Muſhrooms.*

GENERIC CHARACTER.

Fungus roundiſh, fleſhy, firm: becoming powdery and opening at the top. Seeds fixed to filaments connected with the inner coat of the plant.

SPECIES, *&c.*

Only eleven ſpecies are enumerated in Murray's edition of Syſtema Vegetabilium. Dr. Withering has twenty-five Britiſh Species in the third edition of his Arrangement. And ſome of Linnæus's ſpecies are diſpoſed of under other genera. Thus the moſt intereſting of the number, L. Tuber, with the other ſolid Lycoperdons, is ſeparated, and made a diſtinct genus, under its old name of Tuber.

Theſe ſingular Fungi are diſtinguiſhed and deſcribed by Dr. Withering: and are figured by Micheli, Battarra, Batſch, Schæffer, Sterbeck, Schmidel, Bulliard, Bryant, Dickſon, Smith, Sowerby, Bolton, Blackſtone, Dillenius, Vaillant; in the Flora Danica, Ray's Synopſis, Philoſophical Tranſactions, &c. There is alſo an elaborate diſſertation on the Britiſh Stellated Lycoperdons by Mr. Woodward, in the ſecond volume of the Tranſactions of the Linnean Society of London.

LYCOPERSICON. See *Solanum.*

LYCOPODIOIDES. See *Lycopodium.*

LYCOPODIUM. (λυκος ποδιον, *Wolf's-foot, Wolf's-claw Moſs.*)

Lin. gen. n. 1185. *Reich. n.* 1302. *Schreb. n.* 1615. *Dill. muſc.* 441. Selaginoides. *Dill. muſc.* 460. Lycopodioides. *Dill. muſc.* 462. Selago. *Dill. muſc.* 435.

Claſſ. 24. 1. Cryptogamia Miſcellaneæ.
Nat. order of *Muſci* or *Moſſes.*

GENERIC CHARACTER.

Fruſtifications in the axils of the ſcales digeſted into oblong imbricate ſpikes, or of the leaves themſelves, ſeſſile.

Cerf. kidney-ſhaped, two-valved, elaſtic, many-ſeeded. *Veil* none.

SPECIES, *&c.*

Twenty-nine ſpecies are enumerated in Syſt. veget. by Murray. Only ſix of theſe are natives of Britain They are figured by Dillenius and others.

LYCOPSIS (*of Pliny.* Λυκοψις *of Dioſcorides. From* λυκος *a wolf, and* οψις *the face. The corolla being ringent, and having the appearance of a grinning mouth.*)

Lin. gen. n. 190. *Reich. n.* 202. *Schreb. n.* 250. *Gærtn. t.* 67. *Juſſ.* 131. Echioides. *Dill. gen.* 3.

Claſſ. 5. 1. Pentandria Monogynia.
Nat. order of *Aſperifolia. Borragineæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* five-parted: *ſegments* oblong, acute, ſpreading, permanent.
COR. one-petalled, funnel-form. *Tube* cylindric, from curved bent. *Border* half-five-cleft, blunt. *Throat* cloſed with five convex prominent converging ſcales.
STAM. *Filaments* five, very ſmall, at the bending of the tube of the corolla. *Anthers* ſmall, covered.
PIST. *Germ* four. *Style* filiform, the length of the ſtamens. *Stigma* blunt, bifid.
PER. none. *Calyx* very large, inflated.
SEEDS four, longiſh.
OBS. *The eſſence of the genus conſiſts in the curvature of the tube of the corolla.*

ESSENTIAL CHARACTER.

Cor. with the tube bent in.

Buglossum orientale angustifolium, flore parvo cæruleo. *Tournef. cor.* 6.

Leaves ovate quite entire rugged, calyxes upright.

8. Lycopsis virginica. *Virginian wild Buglosse.* *Lin. spec.* 199. *Reich.* 1. 401. *Gron. virg.* 140.

Leaves linear-lanceolate clustered tomentose soft, stem upright.

DESCRIPTIONS, &c.

1. Root annual. It resembles the next species very much, but the stem is prostrate, the root not creeping or abiding, the habit smaller and less villose, the corollas small and brown[1]. Stem angular, hirsute, solid, weak, a long span or more in length. Leaves an inch and half or two inches long, half an inch wide, sessile, lanceolate, pubescent, with a short soft hoary wool. Flowers axillary, from the top of the stem and branches, in swelling hirsute striated calyxes, on short peduncles: corolla very small, scarcely appearing out of the calyx. As the flower withers, the calyx swells very much into a sort of bladder[2].

Native of the South of Europe, in dry hilly situations. It flowers in june and july. Introduced in 1770, by Monf. Richard[3].

2. Root creeping, perennial (or rather biennial). Stem upright, branched. Leaves rough. Calyxes also rough. Corolla small, dark blackish purple. More villose than the preceding[4].

Gærtner conſiders the ſeeds of this natural order as nuts. They are four in number (except when ſome are abortive) in every calyx. Theſe are middle-ſized, cruſtaceous, ovate-acuminate, oblique incumbent on their umbilicus, obſoletely netted-wrinkled above, grooved on the ſides with parallel ſtreaks, ſtraw-coloured, one-celled, valveleſs: aperture of the umbilicus very wide, above the baſe of the nut, on the inner ſide. Seeds ſolitary, that is one within each cell or cruſt, ovate-acuminate, turgidly lenticular, dark or black-brown.

Native of Germany and Auſtria, in dry paſtures, flowering in may and june: with us in june and july. Introduced in 1785, by William Pitcairn, M. D.[5]

3. This plant in reality appears to be the *Asperugo ægyptiaca* of Linnæus. Spec. Pl. edit. 2.]

4. This is a low trailing annual plant, the branches ſeldom extending more than ſix inches, and thinly ſet with ſmall ſpear-ſhaped warted leaves, half ſurrounding the ſtalk. Flowers ſmall, bright blue, collected into ſmall bunches at the extremity of the branches.

[Native of the county of Nice, and the iſland of Candia, on the walls of the city.

It varies with red flowers, elegantly ſtreaked with white. Sir George Wheeler found a variety of it on mount Hymettus near Athens[6].

5. Root annual, ſimple, fibrous, whitiſh. It is an extremely harſh, rough and briſtly plant. Stems thick, cylindrical or ſlightly angular, upright, hiſpid, a foot or more in height, branched for the moſt part at top only. Leaves ſeſſile, lanceolate (ſometimes almoſt linear and ſometimes almoſt ovate,) blunt iſh, hiſpid with hairs iſſuing from ſmall papillæ, paleſt on the under ſide, veinleſs, waved, ſomewhat toothed and rolled back at the edge. Flowers in ſpikes, all one way, ſeſſile and turned backward. Bractes reſembling the leaves. Calyx hiſpid; ſegments oblong or lanceolate, almoſt the length of the corolla. Corolla ſky-blue, border ſlightly divided; ſcales cloſing the throat ſmall, white and hairy. The fruiting calyx cloſes till the ſeeds grow blackiſh, and then opens. Seeds large, nearly black, with a netted-wrinkled ſurface, and a little pointed. Receptacle marked with four round dots hollowed out[7].

The corolla varies, like many others of this colour, to red and white. When the plants grow on dunghills, the leaves are often an inch and half broad.

Native of moſt parts of Europe, in corn fields, eſpecially where the ſoil is ſandy, and on dry banks. It flowers from may to july, as Mr. Curtis ſays: from june to ſeptember, according to Dr. Withering and Mr. Hudſon.

It has lately been recommended as a remedy againſt the Anthrax or corroſive ulcer commonly called a Carbuncle, by laying the bruiſed plant on the tumour; but I find it difficult to perſuade myſelf that ſuch a plant can have any efficacy in ſuch a diſeaſe.

6. Root annual, ſimple. Stems cluſtered, nine inches or a foot high, round, hiſpid, purple, procumbent. Root-leaves numerous, lanceolate-ovate, hiſpid, dark green with prominent white bladders. Stem-leaves ſeſſile, ſomewhat ſtem-claſping, with a few teeth, acuminate. Flowers ſeveral at the extremity of the ſtem. Calyx erect, hiſpid, ferruginous. Corolla at firſt purple, then blue. It differs from the preceding in having the leaves conſtantly bladdery. Common on waſte grounds about Naples; flowering from february through the whole ſummer[8]. It is probably not ſpecifically different from the preceding.

7. This is an annual plant, a native of the Levant.

8. A perennial plant, native of Virginia, by way ſides[9].

PROPAGATION AND CULTURE.

See ANCHUSA. They are hardy plants, will generally riſe from ſcattered ſeeds, and do not bear tranſplanting well.

DESCRIPTION, &c.

1. Root perennial, creeping. This plant has the ſquare ſtalks, oppoſite leaves, inflorescence, flowers and ſeeds of the natural order *Verticillatæ*; differing only in having two ſtamens, whence it is ſeparated in the artificial ſyſtem of Linnæus from its congeners, with which this, as well as Verbena, might be united: Dr. Withering having remarked, that it is not uncommon between the two ſtamens to find two ſhorter filaments without anthers; and that he once found them with anthers.

Stems commonly from one to three feet in height (I have now, Sept. 1. 1797, a ſpecimen before me upwards of four feet high,) upright, the ſides deeply channelled, rough-haired at the corners, branched from the bottom. Branches oppoſite, brachiate, axillary, almoſt erect, the lower ones reaching almoſt as high as the main ſtem. Leaves ovate, ovate-oblong, or almoſt lanceolate, pointed, ſeſſile, ſomewhat wrinkled, ſlightly hirſute, dark green above, pale green beneath, the midrib and veins very ſtrong, the edge cut with deep ſerratures; many of the leaves of the main ſtem, eſpecially the lower ones, pinnatifid at the baſe; theſe are five inches long and two broad; the upper ones and thoſe on the branches are from three to four inches in length, and not pinnatifid, but ſimply ſerrate. Flowers ſmall, many together, diſpoſed in denſe whorls, at each joint, from the axils of the leaves, almoſt from top to bottom of the branches, and in the main ſtem great part of the length. Calyx hirſute, divided into five (ſometimes four) unequal awned cleſts. Corolla white with a tinge of purple, ſomewhat hairy or villoſe within; the upper ſegment ſlightly notched, the lower dotted with purple. Filaments firſt bent in, then ſtraight: anthers ſomewhat creſcent-ſhaped and whitiſh. Germ ſet upon a yellow glandular receptacle. Seeds brown, ſhining, ſubtriangular, outwardly flattiſh, impreſſed with a ſubcordate line in the middle; inwardly the middle running out to a point, and the ſides ſomewhat rolled in.

The leaves vary, in being more or leſs hairy, and more or leſs divided. Mor. 11. 9. 21. Barr. 154. and Pluk. 45. 1. repreſent the variety with jagged leaves. Loers (n. 23.) mentions a variety, with all the flowers female, or without ſtamens. It is common in moſt parts of Europe in meadows, and on the banks of ſtreams and ponds: flowering from july to ſeptember. In ſome meadows it abounds ſo much as to be noxious. Cattle appear not to touch it; and its root being of the creeping kind, renders it difficult of extirpation. It dyes black, and gives a permanent colour to linnen, wool and ſilk. Gypſies are ſaid to ſtain their ſkin with it[a].

Adanſon mentions the two barren filaments. Scopoli remarks its evident affinity to Mentha or Mint. Pollich that there are ſometimes eighty-two flowers in a whorl, with lanceolate bractes under them. His deſcription is a very good one: and ſo is Ray's in his hiſtory.

This common plant, which on trial might probably be found uſeful to dyers, is called by all Engliſh writers *Water Horehound*. In German it is *Waſſerfuſs, Waſſerandorn, Sumpfandorn, Bruchandorn, Waſſermandorn, Waldbrandorn, Waſſerhein, Sparrfaden, Zigeunerkraut, Gliedkraut, Chriſtuskance*. In Dutch, *Waſſpoot. Waterandoorn*. In Daniſh, *Vandnaetru*. In Sweduſh, *Vargfot*. In French, *Marrube aquatique, Licope, Patte de Loup*. In Italian, *Licopo*.

2. Native of Virginia. The leaves are lanceolate and very finely ſerrate[b].

3. Stem the height of a man, branched, angular, rugged. Leaves deeply ſerrate, the loweſt ſerratures deeper, ſo as to be almoſt pinnatifid at bottom, with ſubſerrate ſegments. Corollas four-cleft, white, the ſegments dotted with red, the uppermoſt emarginate, the loweſt broader. Stamens two diſtant. Anthers twin, red.

Native of Italy[c].

I have not ſeen it, but by the deſcription I cannot diſcover any eſſential difference between this and the firſt. Size is nothing.

LYGEUM. (*From Λυγος, Vitex, virga, ſlagrum; a pliant plant, rod, or whip.*)
Lin. gen. n. 70. *Reich. n.* 76. *Schreb. n.* 99. *Juſſ.* 53. *Leeſling.*
Claſſ. 3. 1. Triandria Monogynia.
Nat. order of *Gramina, Graminea* or *Graſſes*.

GENERIC CHARACTER.

Cal. *Spatha* one-leaved, convolute, ovate, acuminate, opening downwards, permanent.
Cor. in pairs, placed on the germ, equal all ways. Glume of the corollet two-valved: outer valve convex, oblong, acute, ſmaller; inner linear, narrow, twice as long, bifid, acute.
Stam. (to each) *Filaments* three, very ſlender, flattiſh, long. *Anthers* linear.
Pist. *Germ* common to both, hirſute, inferior to the corollas. *Style* ſimple, flattiſh, long. *Stigma* ſimple.
Per. *Nut* oblong, extremely hirſute, two-celled, not opening.
Seeds ſolitary, linear-oblong, convex on one ſide, flattiſh on the other.

ESSENTIAL CHARACTER.

Spatha one-leafed. *Cor.* two on the ſame germ. *Nut* two-celled.

SPECIES.

DESCRIPTIONS, *&c.*

Root in moſt of the ſpecies perennial. Stem herbaceous. Leaves oppoſite. Flowers axillary or terminating, ſolitary, or elſe in ſpikes or corymbs[a].

1. Root perennial, creeping. Stem three feet or more in height, when the leaves grow in pairs obtuſely four-cornered; when three together grooved or angular, angles obtuſe; the upper part of the ſtalk ſlightly hairy, the lower ſmooth, branched, and a little thickened at the joints. Leaves in pairs, or three together, (ſometimes four or five) ſeſſile, ovate or lanceolate, pointed, entire but not perfectly even (rather waved) on the edges, veiny, ſmooth or ſometimes woolly. Flowers in terminating axillary racemes, all together forming a panicle. Peduncles ſomewhat viſcid, thickened at top. Diviſions of the calyx ſtriated and edged with red, the tips both before and after flowering twiſted. Corolla yellow. Though the natural number of diviſions in this and the calyx be five, yet ſometimes they are ſix. Filaments unequal, ſhorter than the corolla, viſcid, broad, united at the baſe into a cylinder incloſing the germ. Anthers incumbent, ſubſagittate. Style elongated as the flowers go off. Seeds numerous, very minute[b].

Scopoli remarks, that the corolla has glands on very ſhort pedicels ſcattered over it: that the filaments are alſo glandular, except the tips: that one ſtamen is

[a] Juſſieu [b] Curtis

longer than the reſt, and the contrary: that the anthers are blunt, and have a red ſeptum: that the germ is glandular; the ſtyle thinner at the baſe; and the ſtigma not thicker than the ſtyle.

Native of moiſt parts of Europe, on the banks of ſtreams, and in marſhy meadows; flowering from the end of June to ſeptember.

It has the Engliſh name *Looſeſtrife*, from the quality aſcribed to it by the ancients of quieting oxen when put upon their yokes[a]. So Lyſimachia or Lyſimachus is ſo called ἀπὸ τοῦ λύειν τὴν μάχην, from diſſolving ſtrife. It is alſo called *Willow-herb*, from the ſhape of the leaves. In German it is *Gelbe Weiderich, Gelbes Weidenkraut, Gemeine Lyſimachie, Eſſwurzel*. In Dutch, *Geneeuw Weiderick, Groote Geele Weiderick*. In Daniſh, *Fredloe, Baſtart Duerri, Gaul Gaaſe-beel, Gunlarve*. In French, *Lyſimaque vulgaire, Corneille, Chaſſe-boſſe, Perce-boſſe*. In Italian, &c. *Lyſimachia*.]

2. Root perennial. Stems ſeveral upright, more than three feet high. Leaves narrow, ſmooth; and at the baſe of theſe come out ſhort ſide branches, with ſmaller leaves of the ſame ſhape. The flowers are produced in a long cloſe upright ſpike, at the top of the ſtalk. The corolla is white. Stamens longer than the corolla.

[D'Aſſo thus deſcribes it. Plant three cubits high. Root dividing into ſeveral forks, fibrous, ſpreading horizontally. Stem round, fiſtulous, ſmooth. Leaves lanceolate, quite entire, glaucous. Common peduncles angular. Flowers white, each on its proper pedicel with a linear bractle under it, alternate except at the top, where they are uſually oppoſite. Diviſions of the calyx ovate, with membranaceous edges—of the corolla blunt. Anthers incumbent. Capſule five-valved, containing many angular ſeeds fixed to a dotted receptacle.

It is very diſtinct from the fourth ſort by its ſize, five-valved capſules, white flowers, and leaves without dots. D'Aſſo, taking it to be different from L. Ephemerum, named it *L. Otani*, from Franc. Otano, who firſt detected it in Aragon. The leaves however of our plant are dotted.

Native of Spain. Cultivated in 1731, by Mr. Miller. It flowers from july to ſeptember.

3. Stem erect, four-cornered, ſmooth. Leaves quite entire, acute, ſmooth, dotted. Racemes ſimple. Pedicels in a ſort of whorl, filiform, an inch long. Bractles lanceolate, very ſhort. Diviſions of the calyx lanceolate, ſmooth, dotted with red. Petals three times as long as the calyx, yellow with red ſtripes and dots, and two dark-red ſpots. Stamens ſhorter than the corolla.

Native of North America, in ſwampy ground. Introduced in 1781, by Mr. William Curtis, from Mr. Robert Squibb, then at New York. It flowers in july and auguſt. After flowering, it throws out bulbs from the axils, which falling off in october, produce young plants the enſuing ſpring[b].

4. This is an annual (biennial) plant, too tender for the open air of this country. [It agrees with the ſecond in habit, ſtructure and glaucous colour; but the leaves are not dotted, as in that. L. Ephemerum has the petals blunt and ſpreading, the ſtamens ſhorter than the corolla; the flowers on pedicels: whereas in this there are no dots under the leaves; the petals are acuminate, a little longer than the calyx, converging, and deep red; the ſtamens are longer than the corolla, with brown anthers; and the flowers are ſeſſile in a ſpike: they are however very nearly allied[c].

Native of the Levant. Cultivated in 1759, by Mr. Miller. It flowers in july and auguſt[d].

5. Root perennial, creeping and ſpreading in the mud, bearded with long fibres. Stems in tufts, porous, jointed, round, ſucculent, ſmooth, upright, hardly a foot high in general, but ſometimes near a foot and half; not branched, except that the flowers come out on lateral thyrſes from the axils, towards the top; which Linnæus mentions as a ſingular circumſtance in an upright plant. Leaves linear-lanceolate, marked with many black dots, ſeſſile or half embracing the ſtem, ſlightly pubeſcent beneath, acute, quite entire, about three inches long, and more than half an inch broad towards the baſe; many together at the top of the ſtem. Flowers in oppoſite axillary cylindrical thyrſes or racemes, on pedunicles an inch in length; each ſeparated by a lanceolate bractle. Corolla ſmall, yellow, divided almoſt to the baſe, with very ſhort teeth between the diviſions, which are marked, eſpecially towards the tip, with tawny dots. Stamens much longer than the corolla. The number of theſe, and of ſegments both in the calyx and corolla, varies from five to eight[e].

Native of many parts of Europe, in bogs, marſhes, ponds, ditches, and banks of rivers. In England not common. Near King's Langley in Hertfordſhire. In Angleſea. In Ireland, along the banks of the river at Ballynahinch, above the bridge; found by Mr. John Templeton, of Orange Grove near Belfaſt. Mr. Dodſworth and others have found it in Yorkſhire, but it ſeems to be loſt there.

6. Leaves ovate, acute. Flowers yellow.—Native of Virginia[f].

7. Root perennial, tranſverſe, ſomewhat creeping, bearded with pale fibres. Stems from a foot and half to three feet in height, angular, upright, the ſize of a quill, covered with a ſoft hoary down, leafy, ſeldom branched. Leaves ovate-lanceolate, entire, villoſe on both ſides, ſoft, acuminate, frequently ſpotted with black on the lower ſide, in fours (but ſometimes three or only two) at each joint, on ſhort petioles, from two to three inches long. Pedunicles one-flowered, ſhort, villoſe, axillary, ſeven or eight to a whorl, except towards the top of the ſtem, where there are only two, and on the branches there is one only. Flowers ſmall. Calyx pubeſcent. Corolla yellow; ſegments acuminate with tawny dots at the baſe. Filaments connate, awl-ſhaped at the baſe. Anthers acute, erect, ovate. Capſule globular, ſhining[g].

Native of Holland, among reeds, Auſtria, Sileſia, Piedmont, Siberia. — Cultivated in 1759, by Mr. Miller[h].]

8. Root perennial, creeping. Stalks many, erect, about two feet high. Leaves oblong, oblique, ſmooth, veined on their under ſide, and ending in acute points. Flowers axillary, each on a long, ſlender, naked pedunicle; there are three or four of theſe ariſing from the ſhort branches, which come out on each ſide the ſtalk, at all the upper joints. They are like thoſe of the common ſort, but ſmaller, and hang down.

It was firſt brought from Canada [and is alſo a native of Virginia. Mr. Miller cultivated it in 1759[i]. In Syſt. veget. it is ſet down as a variety of L. quadrifolia; and they are probably the ſame plant.

If this be L. quadrifolia of Gærtner, the capſule is ſpherical, with five lines meeting at the top, one-celled, five-valved. Receptacle globular, fungoſe, excavated, free. Seeds many, but only three or four ripening, roundiſh, very ſlightly convex on one ſide, angular on the other, dotted very cloſely with raiſed dots, ferruginous, navel neutral almoſt obſolete.

9. This is a little annual plant, about two inches, or ſeldom three inches high, from a ſlender, whitiſh, hair-like root. Stems one or two, very ſlender. Leaves ſhort, ending in a very fine point. Flowers ſmall, pale green or herbaceous, ſtellate[k]. Corolla of Centunculus, five-cleft, hence Gerard places it in that genus. Bauhin and others took it for a Linum; but Ray, though he had not ſeen the plant, ſuſpected it not to belong to that genus. Willich (obſ. 91.) could not diſcern either petals or ſtamens. The capſule is ſmall and ſpherical, one-celled, five-valved[l], opening in five parts longitudinally, and not horizontally, as in Centunculus[m]. Receptacle globular, ſtarred a little, fungoſe, white. Seeds two or three, ſeldom more, minute, ovate-globular, mamiform; on one ſide convex and ſtriated tranſverſely; on the other hollowed out with a wide umbilical pit, and grooved radiately, of a ſmoaky colour.

[i] Ibid.
[k] Bauh. prodr.
[l] Gærtner.
[m] Gerard.

Native of France and Italy; flowering in the ſpring. Introduced here in 1776, by Monſ. Thouin. It flowers in June [1].

10. Root perennial, with whitiſh fibres. Stems ſeveral, roundiſh, grooved on each ſide alternately, ſmooth, red, roofing from the lower joints. Leaves gloſſy on each ſide, entire but ſomewhat waved, yelloſwiſh green, dotted with black underneath, the veins a little prominent; eight lines long, ſix or ſeven lines wide; petioles ſhort, broadiſh, grooved above. Peduncles axillary, ſolitary or in pairs, round, one-flowered, ſlender, longer than the leaves. Diviſions of the calyx awl-ſhaped, very ſlender. Corolla yellow, much ſmaller than the leaves (five lines in diameter); at bottom more intenſely yellow and ſhining; in the mouth ſmall yellow glands between the filaments, and little peſticelled glands on the edge of the corolla. Filaments ſmooth, upright, ſomewhat thicker in the middle. Anthers tawny, oblong, bent a little downwards. Germ ſmooth: ſtyle ſomewhat thicker at top. Seeds round and flat.

When the flowers are expanded, they ſomewhat reſemble, in ſhape, thoſe of Anagallis arvenſis or common Pimpernel; hence the older botaniſts conſidered this as an Anagallis. It differs from the next ſpecies, to which it bears no ſmall affinity in its general habit, in having the leaves more pointed, the flowers ſmaller, leſs bell-ſhaped, and on much longer peduncles, and the ſtalks generally redder [2].

Native of many parts of Europe, in moiſt woods, flowering from may to july; or according to Mr. Curtis, from june to ſeptember. Charlton wood. Hanging wood near Woolwich. Shooter's-hill wood. Between Dartford-road and Leeſon-heath. Between Muſwell-hill and Highgate. Cane wood. Scarlet Spring near Hareſield. Stow and Stokenchurch woods in Oxfordſhire. Pychley in Northamptonſhire. Near Nottingham.

11. Root perennial, with ſimple fibres, ſtriking downwards. Stems numerous, ſimple, trailing, putting out roots towards the top and ſometimes a branch; a foot or more in length, ſmooth, jointed, compreſſed, with four membranaceous edges. Leaves ovate-orbicular, upright, ſmooth, ſomewhat veiny, a little waved, on ſhort broad petioles which run down the ſtalk. Peduncles generally two together, oppoſite, upright, the length of the leaves, angular, gradually enlarged towards the end. Calycine leaflets or ſegments cordate-lanceolate, pointed, ſomewhat keeled, reflex at the baſe. Corolla yellow, about the ſame ſize with the leaves; the diviſions ovate, pointed, twice the length of the calyx, ſlightly jagged, and appearing glandular on the edge when viewed with a microſcope. Filaments upright, glandular, ſhorter than the corolla: anthers ſagittate. Style a little longer than the ſtamens [3].

The whole plant is ſmooth. The peduncles are not always equal to the leaves, but ſometimes longer, ſometimes ſhorter [4]. Haller remarks, that the calyx diſtinguiſhes this from all the other ſorts; and that the filaments coaleſce into a hairy circle. Scopoli ſays, the peduncles are five-angled; and that two of the filaments are longer, or one longer than the ſtyle. Polich remarks, that the peduncles have four angles, and are ſhorter than the leaves, but often much longer; that the corolla is half an inch in diameter, and that it frequently has ſmall tawny ſpots on it. Mr. Curtis obſerves, that this plant, like many others that increaſe much by the root or ſtem whilſt they are in flower, ſeldom produces ripe ſeeds. Ray however deſcribes the capſule to be round, very ſmall, and filled with ſeeds ſo minute as to be ſcarcely viſible.

Native of moiſt parts of Europe, in moiſt meadows, on the ſides of ditches, and under hedges in moiſt ſituations; flowering in june and july.

It is called *Nummularia*, ſays Gerarde, of the form of money, wherevnto the leaues are like: in Engliſh *Money-wort*, *Herb Two-pence* and *Twopenny-Graſs*. Other languages have borrowed the ſame circumſtance. In German it is *Pfennighraut*, *Wieſengeld*, *Goldkraut*, *Graſſes gelbes Munzkraut*, *Egelpfenig*, *Egelakraut*, *Kleiner Schlangenkraut*, *Kleines Natterkraut*, *Kleines Mondkraut*, *Waſſerpoley*. In Dutch, *Penningkruid*. In Daniſh, *Pengegraad*, *Pengeblad*, *Kryberde Pengeurt*. In Swediſh, *Penningeört*. In French, *la Lſimaque monnoyere*, *la Nummulaire*, *Herbe aux Ecus*, *Herbe à cent nœux*, *Herbe à cent maladies*. Theſe two laſt names are from *Centumorbia* or *Centummorbia* as it was called by ſome old writers, from its ſuppoſed efficacy in curing various diſeaſes. It was alſo named *Serpentaria*, from a notion that Serpents, when wounded, apply to this herb for cure. In Italian, &c. *Nummularia*.

The leaves are ſubaſtringent and ſlightly acid; hence Boerhaave recommended them in the hot ſcurvy, and hæmorrhages: but modern practice takes no notice of them. According to Linnæus, it is eaten by kine and ſheep, not much relished by goats, and refuſed by horſes. Scopoli recommends an infuſion of the plant in oil for deſtroying Weevils.

12. Root annual, fibrous. Stem filiform, decumbent, from flexuoſe erect at top, villoſe, ſimple, a hand in length. Leaves roundiſh, blunt, entire, very finely villoſe, ſpreading, half an inch in diameter. Petioles double the length of the leaves. Flowers ſeldom ſolitary, generally two together. Peduncles one-flowered, when flowering upright, when fruiting reflex. Native of Japan [5].

PROPAGATION AND CULTURE.

1. 5. 8. Theſe are not often admitted into gardens, becauſe the roots creep ſo much that they become troubleſome; they deſerve a place however for the beauty of their flowers in large gardens, eſpecially in moiſt places, where better things will not thrive. If the roots be taken up in autumn from places where they grow naturally, and planted in a moiſt ſoil, they will thrive without farther care.

2. This is the fineſt ſpecies of this genus, and as the roots of it do not ſpread like thoſe of the other, it deſerves a place in the pleaſure-garden, where it is a very ornamental plant for ſhady borders. It loves a moiſt ſoil and a ſhady ſituation, where it will continue long in beauty. It may be propagated by parting the roots in autumn, but by this method it increaſes ſlowly; ſo that the only way to have it in plenty, is by ſowing the ſeeds: theſe ſhould be ſown upon an eaſt-aſpected border in autumn, ſoon after they are ripe, then the plants will come up the following ſpring; but thoſe which are ſown in the ſpring will not grow the ſame year. When the plants come up they ſhould be kept clean from weeds, and if they are too cloſe, ſome of them may be drawn out and tranſplanted on a ſhady border, which will give the remaining plants room to grow till autumn, when they may be tranſplanted into the borders of the flower-garden where they are deſigned to flower; after which they will require no other culture but to keep them clean from weeds, and dig the ground between them every ſpring.

[3. Increaſes by its bulbs, which it produces inſtead of ſeeds, and requires a very moiſt ſituation [6].]

4. This is propagated by ſeeds, ſown on a moderate hot-bed in the ſpring, often watering the ground to bring up the plants; and if the ſeaſon ſhould prove warm, the glaſſes of the hot-bed ſhould be ſhaded in the heat of the day: when the plants are up, they ſhould have a large ſhare of freſh air admitted to them, to prevent their drawing up weak, and ſhould be frequently refreſhed with water. When they are fit to remove, plant each in a ſeparate pot, plunging them into a moderate hot-bed to forward their taking new root; after which gradually inure them to bear the open air; into which remove them the beginning of june, and let them remain there till october; when they ſhould be removed into a common frame, where they may be ſheltered from froſt in winter, but always enjoy the free air in mild weather. The ſpring following ſome of the plants may be ſhaken out of the pots, and planted in borders: but a few ſhould be put into larger pots, where they may flower and ſeed.

Leaves alternate linear, flowers four-flamened.]
18. Lythrum americanum. *South-American Willow-herb.*
Mill. dict. n. 9.
Salicaria americana, hyssopi folio latiore, floribus minimis. *Houst. MSS.*
Leaves oblong-ovate, below opposite, above alternate, flowers six-flamened.

DESCRIPTIONS, *&c.*

[These are herbaceous, except N. 3, 10, 11. 13 to 15, which are shrubby; more are perennial than annual. Leaves sometimes alternate, but more frequently opposite, or in a sort of whorl. Flowers mostly in several whorls, all together forming a spike, sometimes axillary, subsolitary [a]. The number of stamens differs in several species, and some of them (7, 8, 11, 12, 13.) are separated from Lythrum, and made distinct genera, by Brown, Jussieu, Gærtner, and others.

1. Root perennial thick branched somewhat woody widely extended. Stem from two or three to four or six feet high, upright, tinged with red, below smooth and four-cornered, above pubescent and five-cornered; corners sharp, membranaceous rugged. Upper branches scattered; lower opposite four-cornered rugged and slightly downy upright shortish numerous. Leaves sessile, embracing, about three inches long, smooth above, underneath slightly downy somewhat rugged veined spreading; all opposite, or all alternate, or the lower opposite and the upper alternate. Flowers in clusters, placed at a little distance from each other, in the axils of the leaves, each consisting of about eight flowers, (six to twelve) together forming a long leafy spike. Bracte of the clusters ovate with a long point, underneath villose, longer than the calyx, purplish. Bracte of each flower small, nearly linear, running out to a point. Calyx hairy, truncate, divided into twelve purplish segments, six awl-shaped upright, and six alternate with the others small ovate bending inwards concave and minutely bearded at top. Corolla red purple. Petals oblong wedge-shaped, upright, longer than the calyx, inserted into the edge of it between the longer segments. Filaments inserted into the inside of the calyx; the six longest somewhat longer than the tube of the calyx, the six shortest hid within the tube. Anthers ovate, incumbent; the lower yellow, the upper purple. Dr. Withering remarks, that sometimes a single anther grows to one of the petals; and in this case, besides the twelve perfect stamens, a single filament is found without an anther. Germ superior ovate pointed grooved on each side smooth greenish; style cylindrical scarcely longer than the corolla: stigma capitate. Capsule covered by the calyx, two-celled [b].

Scopoli remarks that there are eighteen flowers in a whorl, that the calyxes are sessile and ten-cornered, the capsule brown, separable from the calyx, and two-celled or three-celled, the seeds wedge-shaped and rufescent, and that the whole plant becomes red as it advances in age.

Pollich says there are twelve or more flowers in a whorl, but in some fewer, that the calyx is marked with twelve streaks.

Krocker observes, that the calyx is not green but white, with twelve red streaks, that the petals are waved, and that the stamens vary in number from six to twelve.

Native of most parts of Europe, in marshes, and on the banks of rivers, ponds and ditches, which it ornaments with its beautiful spikes of purple flowers. Thunberg also found it in Japan, and remarks that it is entirely smooth there. It flowers late in the summer, Linnæus says with Hypericum perforatum or common St. John's wort. It is now in full flower on the 6th of september.

It is astringent, and is recommended by De Haen and several other foreign physicians in long protracted Diarrhœas and Dysenteries. A decoction or the expressed juice is given from one to three ounces. When dried and powdered it imbibes a great quantity of water before it loses its glutinosity. It has been used with success in tanning leather. It seems generally to remain untouched by cattle; Schreber however affirms that they feed on it.

In English it is named Purple spiked Willow-herb or Loosestrife. In German, *Braune Weiderich, Rother Weiderich, Purpur Weiderich, Weidenkraut, Blutkraut, Blauer Fuchsschwanz.* In Dutch, *Partyke.* In French, *Salicaire, Lisimaque rouge.* In Italian, &c. *Salicaria.* In Russian, *Plakun.*

There are several varieties of this handsome plant.

β. One of these is made a distinct species by Mr. Miller.] The stalks are upright and branching, three feet high. Leaves cordate-ovate, an inch long, and three quarters of an inch broad, downy, and placed by threes. Flowers in long spikes, disposed in thick whorls, with spaces between each; they are of a fine purple colour. It is S. purpurea follis subrotundis, *Tourn. inst.* 253. [It is a smaller plant than the common, much more downy, and the leaves broader. We are not told of what country it is a native.

γ. The common sort often varies with three leaves to a joint, in which case the stem is six-cornered.

δ. It has sometimes even four leaves at a joint. Boccone says, the leaves are softer and longer.

ε. Linnæus, in his Flora lapponica, mentions a singular variety, of which he found only a single plant there. The stem a foot high and simple. Leaves alternate, cordate-lanceolate, sessile. Flowers from each upper axil, solitary, sessile.

Mr. Miller has two other species, that seem to be only varieties of L. Salicaria.] 1. Lythrum lusitanicum, n. 4. Salicaria lusitonica, angustiore folio. *Tournef. inst.* 253. It grows naturally in Spain and Portugal, by the side of waters. It seldom grows more than a foot high. Leaves smooth, growing by threes, narrower and shorter than the common sort. Flowers in terminating spikes, of a light purple colour, appearing in july.—2. L. hispanicum, n. 5. Salicaria hispanica hyssopifolia, flor. oblongis saturate cæruleis. *Tournef. inst.* 253. This is also a native both of Spain and Portugal. The stalks are slender, not more than nine or ten inches long, spreading out on every side: the lower part has oblong-ovate leaves, placed opposite: on the upper part the leaves are narrower and alternate. The flowers come out singly from the side of the stalks at each joint, they are larger than those of the common sort, and of a deeper purple colour; they therefore make a fine appearance in july, when they are in beauty.

[2. Root perennial, thick. Stems upright, panicled, from a foot to two feet in length, at bottom hard and woody, round, pale brown mixed with green, commonly without leaves; towards the top green, four-cornered, leafy, with rod-like, axillary, upright, long, alternate branches. Leaves opposite, quite entire, acuminate, never cordate, sattish, an inch and half long, on very short petioles or sessile. Flowers in spikes, of the same colour and size as in the preceding, peduncled, in whorls, six in a whorl, the lower ones more remote, all axillary [c]. Linnæus says, the flowers are two or three, pedicelled, from each alternate axil of the raceme: and that it varies, though seldom, with alternate leaves.

Capsule smooth, ovate-oblong or almost cylindric, obsoletely two-grooved, two-celled, two-valved; the valves when ripe often bifid: partition contrary to the valves. Receptacle linear-oblong, convex, fungose, closely fastened to the partition on each side. Seeds numerous, small, ovate, very much attenuated towards the navel, convex on one side, flat on the other, smooth, pale yellow [d].

Native of Austria, Silesia, Siberia.—Introduced in 1776, by Jos. Nic. de Jacquin, M.D. It flowers from june to september [e].

3. This is a shrub, with a lacerated bark. Leaves

[a] Jussieu. [b] Curtis. [c] Krocker. [d] Gærtner. [e] Hort. kew.

ſeſſile, lanceolate, quite entire. Flowers ſolitary, pedunculed, ſubterminating. Native of China[1].]

4. This riſes with a ſtiff branching ſtalk a foot and half high. Leaves oblong. Flowers in whorls, pale purple, appearing in july. Capſules two-celled. [Peduncles many-flowered, very ſhort. Native of Virginia[2].]

5. This riſes with an upright woolly ſtalk near two feet high. Leaves on ſhort petioles. Flowers axillary, ſolitary, ſmall and pale purple, appearing in july. Native of Virginia.

[Mr. Miller cultivated both theſe before 1759.

6. Stem filiform erect angular, terminated by a larger ſpike, and two ſide ones, which are ſmaller, compoſed of oppoſite remote flowers, with a leaf under each. It has the appearance of L. Hyſſopifolia[3].]

Stalks ſlender, about a foot high. Leaves entire. Flowers axillary, ſolitary, ſmall, white. Calyx ſtreaked, cut into ſix parts at top. It flowers in june, and is a native of Virginia. [This alſo was cultivated by Mr. Miller, before 1759.

7. Roots filiform. Stem proſtrate or creeping, branched, round, ſlender, ſeldom exceeding ten or fourteen inches in length: branches only towards the top, ſimple, alternate, filiform, ſpreading, ſubflexuoſe, round, pubeſcent. Leaves ſmall, oblong, acute, quite entire, ſmooth on both ſides, nerved, on very ſhort petioles. Stipules none. Flowers axillary, eſpecially at the top of the ſtem, ſolitary, ſmall, pale red. Calyx ſwelling a little at the baſe, oblique, ſmooth, the mouth having from ſix to ten teeth. Petals waved. Stigma ſlightly bifid, pubeſcent, white. Capſule two-celled, opening by the calyx being longitudinally cloven in front. Seeds from four to ſix, faſtened by a pedicel to the middle of the receptacle, roundiſh, brown.

Native of Jamaica and Hiſpaniola; flowering the whole year[4].

Dr. Browne, ſuppoſing it to be a new genus, named it *Parſonſia*, after Dr. Parſons, who publiſhed a treatiſe on the ſeeds of vegetables, and many other curious remarks on different parts of natural hiſtory[5]. Juſſieu keeps it ſeparate from Lythrum, under the name which Browne had given it: the calyx being ventricoſe and only ſix-toothed; ſtamens only ſix, ſhort ſo as not to ſtand out of the corolla; capſule ſmall, membranaceous, covered by the calyx, one-celled (two-celled), containing few ſeeds (two to ſix), faſtened to a central receptacle. The flowers are axillary, alternate and ſolitary.

8. This is a weakly plant, with a ſlender ſtem well ſupplied with branches towards the top; and having a diſagreeable ſharp ſmell, approaching much to that of Guinea Henweed, but more ſubtile, and leſs perceptible when placed cloſe to the noſe. The leaves and flowers are much like thoſe of the preceding, as well as the diſpoſition and make of the capſule; but that plant does not branch ſo much, nor has it any thing of this ſmell[1].

Stem almoſt a foot high, ſubdivided, aſcending, roundiſh, rugged. Leaves petioled, large, acute, quite entire, nerved, ſomewhat rugged. Flowers pedunculed, ſolitary, axillary, larger than thoſe of the preceding ſort, purple. The calyx has from ſix to ten teeth. Petals ovate, deciduous. Filaments eight to ten, unequal, ſhort, inſerted below the middle of the tube: anthers cordate. Stigma acute. Seeds four to ſix, faſtened to a pedicel, emitted by the burſting of the calyx, ovate, compreſſed. Diſtinguiſhed by the alternate ſituation of the flowers[6]. But is not that circumſtance common to this and the preceding ſort? Native of Jamaica, in the cane-pieces. I ſuppoſe Browne's name is given on account of its ſmell. If Parſonſia ſhould be ſeparated from Lythrum, this will accompany it.

9. Native of Hiſpaniola.

10. Native of Jamaica. Theſe are both ſhrubby[7].

11. Root fibrous, annual. It has a deſicate ſlender ſtalk, round, upright, ten inches or a foot in height, pubeſcent, purple: branches few, alternate, ſimple. The whole plant is extremely viſcid all over. Leaves quite entire. Flowers lateral, on very ſhort peduncles, ſolitary, decumbent. Calyx twelve-ſtreaked, ſix-toothed, the upper tooth wider. Petals unequal, the two upper ones larger. Nectary a reflex ſcale, within the prominent part of the calyx. Stamens twelve, unequal by inſertion, eight coordinate and of the ſame ſhape, four ſmaller in two rows, the two upper ones villoſe: anthers roundiſh. Capſule oblong, one-celled, covered by the calyx, cloven along with it, and then boat-ſhaped; the receptacle with the unripe ſeeds coming forth and riſing, in order to ripen the ſeeds in the open air, after the manner of Phryma[8]. The ſeeds are few, from five to ten, ovate-rounded, lens-ſhaped, with a right line on one ſide ending in a very minute caruncle, of a teſtaceous brown colour[9]. It differs from Lythrum in having a ſix-toothed unequal calyx; ſix (or five) unequal petals; and a one-celled capſule without valves, burſting by the enlargement of the receptacle: hence Juſſieu, Gærtner and others, following Browne, have made it a diſtinct genus under the name of *Cuphea*, but Schreber not having taken it up, I have left it here.

Native of America, as Braſil and Jamaica; introduced in 1776, by Joſ. Nich. de Jacquin, M.D. It flowers in july and auguſt[8].

12. Root perennial. Eaſily diſtinguiſhed from the reſt by its filiform peduncles, terminated by two lanceolate channelled ſpreading bractes, longer than the flower, and between theſe three regular flowers, on ſhort pedicels, blue and ſmall[1].

Juſſieu doubts whether this, which is the *Noſea* of Commerſon, really belongs to this genus. According to him the leaves are oppoſite, the peduncles oppoſite axillary three-flowered, the calyx ventricoſe with from eight to ten teeth, the corolla four or five-petalled, with from eight to ten ſtamens, and the fruit two-celled. Native of America.

13. This is a hoary ſhrub. Leaves approximating, at the tops of the branches. The calyx has twelve unequal toothlets. Petals white. Stamens twelve. Capſule turbinate.

It appears to be of a different genus on account of its one-celled circumciſed fruit, but if one difference be deemed ſufficient to conſtitute a ſeparate genus, genera will be multiplied too much; and natural genera ought as much as poſſible to be kept entire[4].

Forſter has given it under the name of *Pemphis*, from *Πεμφις, bulla*, which the globular germ repreſents. According to him, the capſule is one-celled and ſix-valved, the ſeeds angular, compreſſed, faſtened to a ſhort three-toothed receptacle at the bottom of the capſule; in other reſpects the characters agree with thoſe of Lythrum: and in his Florula he has given it under Linnæus's name.

Found by Koenig on the coaſt of Ceylon, and by Forſter in the iſland of Teautea in the South Sea.

14. This is a ſuffruticoſe plant. Leaves quite entire, veined. Racemes long, from the forks, or terminating. Flowers remote, in pairs, pedicelled, erect, with ovate bractes. The ends of the twigs, the calyxes and pedicels have clammy hairs.

15. This is a ſhrub with alternate branches. Leaves quite entire, very rugged with ſhagginеſs on both ſides, ſhining on the upper; the lower in whorls, by fours or threes, on the branchlets oppoſite. Flowers pedicelled. Calyx linear, hiſpid, viſcid. Petals large, inſerted into the upper margin of the calyx, erect, obovate, violet or blue. This ſpecies is very diſtinct on account of its flowers, which are handſome. Both theſe were found in South America by Mutis[1].

16. Root annual. (Mr. Miller ſays perennial.) Stems proſtrate, ſhiffiſh, ſimple or branched only near the root, rod-like. Leaves numerous, ſeſſile, blunt, quite entire. Flowers axillary, ſolitary, ſubſeſſile, ſmall, blue. (Linneus ſays purple, white at the baſe;

[1] Linn. [2] Ibid. [3] Ibid. [4] Swartz. [5] Brown. jam. [6] Browne. [7] Swartz. [8] Ibid.

[1] Lin. ſuppl. & Browne. [2] Gærtner. [3] Hort. kew. [4] Linn. ſuppl. [5] Ibid. [6] Ibid.

Miller. light purple.) Calyx tubular, with five or ſix ſpreading teeth. Stamens ſhorter than the calyx *.

Scopoli ſays, the ſtem is half a foot long; the branches angular; the calyx cylindric, ſtreaked, ſmooth, twelve-toothed; the teeth alternately ſmaller and upright; the capſule four-celled, four-grooved, blunt, incloſed in the calyx, ruſeſcent, cylindric; the ſeeds roundiſh, as many as fifty-ſix in one cell. The fruiting calyxes are preſſed to the ſcape.

Pollich remarks, that though the flowers are ſolitary, yet that ſometimes there are two together ſitting cloſe in the axil of a leaf; that the calyx is ſix-toothed, and that the teeth are ſhort pointed ſpreading, and red at the tip.

Mr. Miller ſays that the ſtems are a foot, and Monſ. Villars that they are two feet long. The latter remarks that the leaves are very bitter.

Krocker affirms, that the ſtems are ſuberect, not properly decumbent, and that they are a foot or more in length, quadrangular, with ſimple ſuberect brachiate branches from the baſe. Leaves glaucous-green, ſmooth, on very ſhort petioles or ſeſſile, an inch long and two lines wide. Flowers one, or two alternate. Calyx ſix or twelve-cleft; diviſions triangular, ſix broader upright, ſix ſmaller reflex. Petals five or ſix, roſe-coloured, ovate-lanceolate, inſerted into the edge of the calyx between the ſegments, fugacious. Stamens ſix or eight. Capſule cylindric, contained within the calyx, two-celled.—Part of this deſcription is from Haller.

Native of many parts of Europe, as Germany, Switzerland, Auſtria, France, Italy, England, in wet meadows, watery places, and eſpecially where water ſtagnates in winter; but it does not ſeem to be very common any where. With us it is found on Hounſlow heath. Between Staines and Laleham. On Hiſton, Hinton and Teevertham moors, and at Oakington in Cambridgeſhire. On the Banbury road from Oxford, near the firſt turnpike gate. Feverſham in Kent, in the ditches near the Abbey pond. Near the Wheatſheaf, five miles beyond Huntingdon on the north road. About Wilford in Northamptonſhire: flowering in july and auguſt. In Engliſh it is called *Graſs-Poly* or *ſmall Hedge-Hyſſop*.

17. Root annual. Very like the preceding, but only half or one third of the ſize. Stems, according to Villars, creeping, five or ſix inches long, with others ſmaller ſpringing from their centre, which have ſeveral alternate branches. Krocker ſays the ſtem is upright, with ſometimes a branch or two, but commonly ſimple. Leaves ſmall, pointed, very dark green, the lower ones oppoſite, the reſt alternate. Flowers ſolitary, axillary, ſeſſile, very ſmall. Calyx ſmall, angular, commonly four-toothed, but ſometimes though rarely five-toothed, ſupported by two lateral ſtipules. Petals commonly four, roſe-coloured. Stamens commonly four, ſometimes two or five. The number of theſe and of the petals correſponding with the diviſions of the calyx. The flowers are much ſmaller than in the preceding ſort *.

Native of the South of France, Italy, Sileſia, &c. in moiſt meadows and ditches; flowering in auguſt. Krocker ſuſpects that it may be a variety of the preceding.]

18. This has a woody root, from which ariſe two or three ſlender ſtalks upwards of two feet high. Leaves ſmooth. Flowers from the upper axils, ſolitary, ſmall, white, ſix-petalled. They do not appear till the ſecond year from ſeed. It was diſcovered by Dr. Houſtoun at La Vera Cruz, in ſwamps: and was cultivated by Mr. Miller before 1733, but has been ſince loſt.

PROPAGATION AND CULTURE.

1. The firſt, with its varieties, may eaſily be cultivated by parting the roots in autumn, but ſhould be planted in a moiſt ſoil. It is a handſome plant, and deſerving of a place in large gardens and plantations.

2. 4. 5. 6. The other hardy foreign ſorts may be increaſed in the ſame manner. When raiſed from ſeed, the ſeeds ſhould be ſown in autumn; otherwiſe they will remain a year in the ground.

3. 7. 8. 9. 10. 11. 12. 13. 14. 15. 18. Theſe are too tender to live in the open air. Sow the ſeeds in pots, and plunge them into an old hot-bed. They will not riſe unleſs they are ſown in autumn. Shelter them through the winter, and in ſpring place them in a freſh hot-bed. Treat them as other tender plants from hot countries.

16. 17. Being annual, muſt be raiſed from ſeeds: but they are bog plants, and ſeldom cultivated in gardens.

SPECIES.

1. Maba elliptica.

Forſt. gen. 122. *flor. auſtral. n.* 366. *Lin. ſyſt.* 881. *ſuppl.* 426.

DESCRIPTION, *&c.*

This is a very ſmooth tree, with the twigs and young leaves hairy. Leaves alternate, on very ſhort petioles, elliptic, veined, very ſmooth. Pedunckes axillary, ſhort, often three-flowered. Flowers ſmall, and ſingular in having the outſide of the calyx and corolla more villoſe than any of the plant *. Native of the Friendly iſlands.

There is another ſpecies or variety, which Forſter calls *Maba major*, becauſe the drupe or fruit is three times the ſize of the other, having three-ſided kernels in the cells, which are tough and inſipid; they are however eaten by the inhabitants, and were brought for ſale to our people. In all the Friendly iſlands they plant the tree about their houſes *.

DESCRIPTIONS.

1. This is a ſhrub, of which the trunk is ſix feet high; and about ſix inches in diameter. From the trunk riſe ſeveral twiggy branches to a great height, which ſpread and catch upon the neighbouring trees. The leaves are alternate, ſmooth, green above, white below: the foot-ſtalk ſhort, and furniſhed with two long and ſtraight ſtipules, which are deciduous. The flowers are borne in great numbers on the tops of the branches, ranged in a long panicle: the males are on the upper part of the panicle, the females on the lower, and are about eight or ſix in number. All the parts of this ſhrub yield a milky juice. The Creoles and Negroes uſe the ſmaller branches for pipes; for which reaſon the tree is called Pipe wood (Bois a Calumet.)

2. This differs from the preceding in having a reddiſh bark; and the leaves larger, green above, and veined with red beneath: the largeſt are three inches and a quarter long, and an inch and quarter wide. The fruit is much larger than the former. In other reſpects it is like the former, and the branches are put to the ſame uſe.

3. Macrocnemum candidiſſimum.
   Vahl. ſymb. 2. 38. *t.* 30.
   Corymbs trichotomous with roundiſh leaves, leaves ovate.

DESCRIPTION, *&c.*

1. This is a ſmall tree, with a branching ſmooth trunk. Branches long, looſe, round, warted. Leaves approximating, towards the upper part of the branchlets petioled, oppoſite, large, oblong, with a ſhort point, entire, nerved, ſmooth on both ſides. Petioles ſhort thickiſh round ſmooth. Flowers in a ſort of panicle. Peduncles axillary oppoſite longer than the leaves round compreſſed ſmooth, three-parted above, with trichotomous branchlets, the laſt one-flowered. Corollas rather large, of a yellowiſh green: tube half an inch long, regular, narrower at the throat, before opening five-cornered, then cylindric: diviſions of the border acute, almoſt upright. Filaments the length of the tube, from the baſe above the middle very hairy, a little inclined. Anthers vertical oblong tawny. Germ obconical ſmooth[a].

Browne obſerves, that this tree riſes generally to the height of twelve or fourteen feet. It is a native of the ſouthern part of the iſland of Jamaica, on the banks of rivulets.

2. This is a tree with hairy branches. Leaves petioled, a foot long and a hand wide, narrowed at the baſe, broader outwards, membranaceous, quite entire, ſmooth above, the midrib hairy underneath. Raceme terminating, a foot long, peduncled, compoſed of ſmall oppoſite peduncled corymbs: partial peduncle hirſute trifid: lateral pedicels five-flowered; middle one trifid. Bracte at the baſe of the partial peduncles ovate, acuminate, concave, ciliated: bracte of the pedicels lanceolate, rough-haired. The five clefts of the calyx are rounded. There is a petioled leaflet, an inch and half long, elliptic purple, netted veined, ſmooth, to each corymb, as in Muſſœnda frondoſa. Corolla funnel-form: diviſions lanceolate, blunt, ſmooth: tube twice as long as the calyx. Filaments in the jaws of the tube, the length of the corolla, hairy within: anthers linear, reaching beyond the corolla. Germ turbinate, angular, hirſute: ſtyle thickened, the length of the corolla: ſtigmas two, blunt, reflex. Seeds membranaceous, awl-ſhaped, faſtened to a linear receptacle. Can this be a Macrocnemum, with the corolla not bell-ſhaped? It certainly agrees with that genus in moſt circumſtances. It differs from Muſſœnda in the fruit. Found in the iſland of Trinidad by von Rohr.

3. This is a tree with round ſmooth oppoſite branches, jointed at top, compreſſed, dilated under the leaves. Leaves petioled, two inches long and more, oppoſite, acuminate, blunt, veined, quite entire, ſmooth above, paler underneath, villoſe along the veins. Peduncles from the tops of the branches in threes, ancipital, dilated at top, twice trifid. Leaflets two, ſmall, under the firſt diviſion of the peduncles. Partial peduncles of the ſame ſtructure with the common peduncle. Pedicels three-flowered: the lateral flowers ſubpedicelled, the middle flower ſeſſile. There is a petioled leaf, obovate or roundiſh, an inch long, membranaceous, netted-veined, very white, from the margin of the lateral calyxes of the corymb, two in each corymb. Capſule oblong, ſomewhat flatted, two-grooved, each valve having a raiſed line along it. Found by von Rohr in the neighbourhood of St. Martha[b].

MACROLOBIUM. (*So named probably from having one of the petals very long in proportion to the others.*)

Lin. gen. Schreb. n. 62. Outea. *Aubl. guian. t.* 9. *Juſſ.* 347. Vouapa. *Aubl. t.* 7. *Juſſ.* 350.

Claſſ. 3. 1. Triandria Monogynia.

Nat. order of *Lomentaceæ.—Leguminoſæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* double. *Outer* two-leaved: *leaflets* oppoſite, ovate-oblong, faſtened to the baſe of the inner. *Inner* one-leafed, turbinate, ſhort: *mouth* oblique, five-toothed.

[a] Swartz. [b] Vahl.

Cor. five-petalled, unequal. *Upper petal* very large, upright, clawed, oblong, blunt, concave, waved, inserted into the inner perianth. *Lower petals* four, small, ovate, spreading, fastened to the inner perianth above.

Stam. *Filaments* four, inserted into the inner perianth, one from barren, under the great petal: three very long, filiform, anther-bearing, fastened below the smaller petals. *Anthers* four-cornered.

Pist. *Germ* pedicelled, ovate. *Style* filiform. *Stigma* blunt.

Per. *Legume* ovate, compressed, coriaceous, one-celled.

Seed single, roundish, compressed.

Obs. Outea and Vouapa *of Aublet, seem to be of the same genus, since in both, the corolla, fertile filaments and pistil, agree in number figure and situation of parts; though in the former Aublet did not find the ripe fruit, and in the latter has not distinguished the smaller petals from the calyx. Jussieu however has kept them separate.*

ESSENTIAL CHARACTER.

Cal. double: outer two-leaved: inner one-leafed. *Pet.* five: upper very large, the four others very small, equal. *Germ* pedicelled. *Legume.*

SPECIES.

1. M. Vouapa. With binate leaves; the legume sharp on one side, and two-winged.
2. M. Simira. With binate leaves; the legume rounded on all sides.
3. M. Outea. With two-paired leaves (foliis bijugis.)

DESCRIPTIONS, *&c.*

1. This is a tree sixty feet high, very much branching at the top, with scattered branches and branchlets: the leaves are alternate, green, strong, and thick; oval, and terminated by a long point: the largest are about five inches long, and two broad. The flowers grow on a little sprig from the bosoms of the leaves at the ends of the branches: they are large, and of a pale violet-colour. It grows in the large forests of Guiana.

2. This is a tree of eighty feet high, with a very thick trunk, much branched at the top: the bark is reddish, thick, and wrinkled. Leaves smooth, entire, green, the flowers were not observed by Aublet.

3. A tall tree, rising to fifty feet, with a smooth, gray bark: very branchy at top: branches some rising, others hanging; leaves alternate: their wings smooth, strong, green, oval, and obtuse: from the bosoms of the leaves spring the spikes of flowers about three inches long: these flowers are alternate, solitary, and borne each on a peduncle of different length in different flowers, and furnished at the base with a small scale. Grows in forests in Guiana.

DESCRIPTIONS, *&c.*

[These are trees, chiefly natives of North America, none of Europe. The leaves are large, and the flowers are axillary, very large, and odorous.]

1. The Great laurel-leaved Magnolia or Tulip-tree, in the Southern Provinces of North America, rises with a straight trunk of two feet or more in diameter to the height of seventy or eighty feet, or more, dividing into many spreading branches, that form a large regular head. The leaves are nine or ten inches long, and three inches broad in the middle, of a thick

conſiſtence, reſembling thoſe of the common Laurel, but much larger, entire but a little waved on their edges, of a lucid green on the upper ſurface, and ſometimes ruſſet-coloured underneath; they are ſeſſile, placed without order on every ſide the branches, and continue green throughout the year, falling off only as the branches extend, and new leaves are produced. The flowers are produced at the ends of the branches: they are very large, and compoſed of eight or ten petals, narrow at their baſe, but broad rounded and a little waved at their extremities; they ſpread open very wide, are of a pure white colour, and have an agreeable ſcent.

[The fruit is compoſed of many capſules diſpoſed in form of a ſtrobile; they are triangular, compreſſed wedge-ſhaped, coriaceous, one-celled, the outer ſide thickened, corky, pubeſcent; they gape open, and each cell is lined with its own papery membrane, and is accompanied at its lower and anterior margin with the ſtyle converted into a woody briſtle. Common receptacle long, roundiſh, covered all over with the capſules placed vertically. Proper receptacle a filiform umbilical chord, becoming finally very long, fringing from the inner angle of the capſule. Seeds regularly two to each capſule, but ſometimes only one, parabolical, plano-convex or obſoletely angular, berried, ſcarlet [a].]

The ſummers in England are not warm enough to bring the fruit to perfection, though ſome old plants often form ſtrobiles. This tree in its native country begins to produce flowers in may, and continues a long time in flower, ſo that the woods are perfumed with their odour the greateſt part of the ſummer: but in England it ſeldom begins to flower till the middle or end of june, and does not continue long in beauty.

This fine tree is a native of Florida and Carolina, and in common with many of the trees and plants of that country, is impatient of cold here, and difficult to keep in perfection, either abroad or houſed. If it can be ſo far naturalized as to endure the cold of our ſevere winters in the open air, it will be one of the greateſt ornaments to our plantations. The time when it ſuffers moſt is by the early froſts in autumn, the extremities of the ſhoots being then tender.

[In the Kew catalogue, it is ſaid, from Cateſby, that the Laurel-leaved Magnolia was cultivated before 1737, by Sir John Colliton.] Mr. Miller relates that there were a great many young plants in England before the year 1739; that a great part of theſe were deſtroyed by that ſevere winter; and that ſince, few good ſeeds have been ſent to England, ſo that for many years after few of the plants were to be ſold in the nurſeries. He had however a pretty large plant, which having been apparently killed by the ſevere winter of 1739-40, he cut down to the ground after midſummer, and the root ſhot up again the year after. He ſays that the largeſt tree of this ſort which he had met with in England was in the garden of Sir John Colliton of Exmouth in Devonſhire; he alſo mentions a very handſome plant in Mr. Chriſtopher Gray's nurſery near Fulham; and many large thriving trees at Goodwood in Suſſex, the ſeat of his Grace the Duke of Richmond.

[2. Native of the iſlands of St. Lucia, Martinico, and Guadaloupe, in the Weſt Indies [b].] Mr. Miller remarks, that if Father Plumier's figure of the ſection of his fruit be exact, his muſt be a different genus from this; the ſeeds being repreſented within the fruit, lying round a column.

3. Swamp Magnolia uſually grows about fifteen or ſixteen feet high, with a ſlender ſtem, covered with a ſmooth whitiſh bark. The wood is white and ſpongy. Leaves thick and ſmooth, reſembling thoſe of the Bay, [entire, dark green on their upper ſurface, but whitiſh or glaucous, and a little hairy underneath.] The flowers are produced in may and june at the extremity of the branches; they are white, and have an agreeable ſweet ſcent; and have only ſix concave petals. After theſe are paſt the fruit increaſes to the ſize of a Walnut with its cover [an inch or more in length, and three fourths of an inch in diameter] of a conical ſhape: the ſeed is about the ſize of a kidney-bean. This fruit is at firſt green, afterwards red, and when ripe, of a brown colour. In North America, where it grows naturally in low moiſt or ſwampy ground, there is a ſucceſſion of flowers on the trees for two months or more: but in England there are ſeldom more than twelve or fourteen flowers on a tree, and thoſe of ſhort duration.

The young plants frequently retain their leaves through the greateſt part of winter, and often do not fall, till the young ſhoots thruſt them off; but when they are three or four years old, they conſtantly caſt their leaves by the beginning of november.

[In the Kew catalogue however the *deciduous* is diſtinguiſhed from the *evergreen* Swamp Magnolia.]

The greateſt number of theſe trees, which are now growing in England, are at his Grace the Duke of Norfolk's, at Worklop Manor, in Nottinghamſhire.

[It was cultivated in 1688, being inſerted by Ray in his catalogue of rare exotic trees and ſhrubs, cultivated in the epiſcopal garden at Fulham, by Biſhop Compton, to whom it was ſent by Baniſter [c].

In America this tree is known by the names of *White Laurel*, *Swamp Saſſafras*, and *Beaver-Tree*. It has the laſt name, becauſe the root is eaten as a great dainty by Beavers, and this animal is caught by means of it. Kalm ſays that this tree drops its leaves early in autumn, though ſome of the young trees keep them all the winter. This correſponds with what Mr. Miller affirms, as ſtated above. Kalm alſo reports, that he has ſeldom found the Beaver tree to the north of Penſylvania, where it begins to flower at the end of may. Theſe trees may then be diſcovered by the ſcent of the bloſſoms at the diſtance of three quarters of a mile, if the wind be favourable. It is beyond deſcription pleaſant to travel in the woods at that ſeaſon, eſpecially in the evening. They retain their flowers for three weeks, and even longer. The berries alſo look very handſome, when they are ripe, being of a rich red colour, and hanging in bunches on ſlender threads. They cure coughs and other pectoral diſeaſes by putting theſe berries into brandy, and giving a draught of the liquor every morning; it is even ſaid to have ſalutary effects in conſumptions. A decoction of the bark alſo, or an infuſion of it in brandy, is ſaid not only to eaſe pectoral diſeaſes, but to be of ſervice againſt internal pains and heat, and it is thought that it will ſtop a dyſentery. For a cold they commonly boil the branches in water.—The wood is made uſe of for joiner's planes [d].—Dillenius uſually obſerved eight petals in the corolla; and remarks that the flowers never open in a morning, that the calyx falls off at the ſecond opening of the flower, but that the petals dry on, and that the ſcent reſembles that of Lily of the Valley, with a mixture of aromatic.

4. The leaves of this are obovate-oblong, entire, ſmooth, from a hand to a foot in length, with the nerves underneath villoſe.

5. The leaves are elliptic-lanceolate, acute, petioled, entire, ſmooth above, ſilky tomentoſe underneath, a hand in length. Peduncles ſhort, reflex, grooved, thick, tomentoſe. Both are natives of Japan, and were originally ſuppoſed by Thunberg to be the ſame with M. glauca of America. They are cultivated by the Japaneſe for the elegance of the flowers [e].

6. This tree grows ſometimes to the height of thirty or forty feet, and the trunk is eighteen inches or more in diameter.] Leaves near eight inches long, and five broad. The flowers come out early in the ſpring, are compoſed of twelve [large whiſh-coloured petals. The fruit is about three inches long, ſomewhat reſembling a ſmall Cucumber, whence the inhabitants of North America call it Cucumber Tree [f].] The wood is of a fine grain, and an orange colour. It is not very common in any of the inhabited parts of America. Some of the trees were diſcovered by Mr. John Bartram, growing on the north branch of Suſquehannah river. [It was introduced in 1736, by Mr. Peter Collinſon [g].]

[a] Gærtner. [b] Swartz. [c] Hiſt. p. 1798. [d] Kalm. [e] Thunb. in Linn. tranſ. & jap. [f] Marſhall. [g] Hort. kew.

7. The Umbrella tree uſually grows from ſixteen to twenty feet high, with a ſlender trunk, [covered with a ſmooth bark, and dividing into ſeveral branches.] The leaves are remarkably large, [often from twelve to fifteen inches or more in length, and five or ſix in width, narrowing to a point at each extremity, placed at the ends of the branches in a circular manner, ſomewhat like an Umbrella, whence its name. The flowers are compoſed of ten, eleven or twelve large, oblong, white petals, the outer ones hanging down. Seed-veſſels oblong, conical, between three and four inches in length, and about an inch and half in diameter[1].]

The wood is ſoft and ſpongy; and the leaves drop off at the beginning of winter.

This is pretty frequent in Carolina. It is alſo found in Virginia, [and ſome parts of Penſylvania. It was cultivated here in 1752, according to Miller[2].]

PROPAGATION AND CULTURE.

The Magnolias are propagated by ſeeds, procured from the places of their natural growth: theſe ſhould be put up in ſand, and ſent over as ſoon as poſſible; for if they are kept long out of the ground, they rarely grow, and therefore ſhould be ſown ſoon after they arrive. It is a good way to ſow them in pots, and plunge them into an old hot-bed of tanner's bark.

They may alſo be raiſed from layers and cuttings, but theſe do not thrive ſo well as thoſe which come from ſeeds, nor will they grow to near their ſize.

1. The firſt ſort is not ſo difficult to train up as the third, but in order to get the plants forward, it will be proper when they are removed out of the ſeed-pots, to plant them each into a ſeparate ſmall pot, filled with ſoft loamy earth, and plunge them into a gentle hot-bed of tanner's bark, obſerving to ſhade them from the ſun, and admit proper air to them; but in midſummer, if they are well rooted, inure them to the open air gradually, and place them in a ſheltered ſituation, where they may remain till autumn; but on the firſt approach of froſt remove them under ſhelter. When the plants have got ſtrength, ſome of them may be turned out of the pots, and planted in the full ground in a warm ſheltered ſituation; but part ſhould be kept in pots, and ſheltered in the winter, leſt thoſe in the open air ſhould be killed.

If the plants make good progreſs, they will be ſtrong enough to plant in the full ground in about ſix or ſeven years from ſeeds. Remove or ſhift them in march, before they begin to ſhoot; which may ſometimes happen to be too ſoon to turn them out of the pots into the full ground; but as there will be no danger in removing them out of the pots, the ball of earth being preſerved to their roots, it is beſt to defer this till the month of april: but it will be neceſſary to harden thoſe plants which are intended to be planted out, by expoſing them to the air as much as poſſible before, which will keep the plants back, and prevent their ſhooting: for if they make ſhoots in the green-houſe, they will be too tender to bear the ſun, until they are by degrees hardened to it, and the froſts which frequently happen very late in the ſpring will greatly pinch them.

Two or three winters after they are planted out, it will be neceſſary to lay ſome mulch on the ſurface of the ground about their roots, as alſo to throw ſome mats over their heads, eſpecially at the beginning of the morning froſts in autumn: but in doing this, the heads of the plant ſhould never be too cloſely covered up, leſt the ſhoots ſhould grow mouldy, which will be as injurious to them as the froſt. As the plants get ſtrength, they will be better able to endure the cold of our climate; though it will be proper to lay ſome mulch about their roots every winter, and in very ſevere froſt to cover their heads and ſtems. [This is beſt done by erecting an occaſional frame of poles, whereon the mats may be thrown, which by being at a diſtance from the plant, will not confine it, or bruiſe the tender ſhoots; and they may be put aſide in the day time towards the ſun, or from the wind.]

3. When the Swamp Magnolias are tranſplanted from the place of growth into dry ground, they make handſomer trees, and produce a greater number of flowers: this however is to be underſtood of America, for in Europe they do not thrive ſo well in a dry ſoil as in a moiſt loam.

This and the other deciduous ſorts are not ſo tender as the firſt, but will endure the cold very well, after they have once acquired ſtrength: for as they loſe their leaves in the winter, the froſt has not ſo much power over them as over the firſt, whoſe leaves are frequently tender towards the ends of the ſhoots, eſpecially when it grows freely, or ſhoots late in the autumn.

[In increaſing theſe trees by Layers, chooſe the young pliable ſhoots, giving them a gentle twiſt or a ſlit. It may be done either in ſpring or autumn. Some may root in one year, but more probably not till the ſecond. Take them off in march, plant them in pots, and plunge them in a moderate hot-bed for a month or two, and thus they will make good plants by autumn. Shelter them during winter for a year or two, and then plant them in the full ground.

For Cuttings, take ſhort young ſhoots of the preceding year; in march or april plant them in pots; plunge the pots up to the brims in a hot-bed; water and ſhade them occaſionally; and when they are rooted inure them by degrees to the open air.

MANAGOKI. See *Swietenia*.

MAHALEB. See *Prunus*.

MAHERNIA.

Lin. gen. Reich. n. 424. Schreb. n. 534. Juſſ. 290. Cavan. diſſ.

Claſſ. 5. 5. Pentandria Pentagynia.

Nat. order of *Columniferæ. Tiliaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-cleft, bell-ſhaped; with awl-ſhaped longer teeth: permanent.

COR. *Petals* five, heart-ſhaped, oblong, ſpreading, twice as long as the calyx.

Nectaries five, obcordate, pedicelled, ſurrounding the germ, ſhorter than the calyx.

STAM. *Filaments* five, capillary, placed on the nectary, united at the baſe, ſhorter than the calyx. *Anthers* oblong, acuminate, erect.

PIST. *Germ* ſubpedicelled, obovate, five-angled. *Styles* five, briſtle-ſhaped, erect, the length of the petals. *Stigmas* ſimple.

PER. *Capſule* ovate, five-celled, five-valved.

SEEDS few, kidney-form.

OBS. *It has a very great affinity to* Hermannia, *but their nectaries cannot be combined in the ſame character.*

ESSENTIAL CHARACTER.

Cal. five-toothed. *Pet.* five. *Nect.* five, obcordate, placed under the filaments. *Capſ.* five-celled.

SPECIES.

1. Mahernia verticillata. *Whorl-leaved Mahernia.*
Lin. ſyſt. 308. *Reich.* 1. 776. *mant.* 59.
Leaves in whorls linear.

2. Mahernia pinnata. *Wing-leaved Mahernia.*
Lin. ſyſt. 308. *Reich.* 1. 776. *Curt. magaz.* 277. *Comm. rar.* t. 7. (Ketmia) *Pluk. mant.* t. 244. f. 3. (Ciſtoides)[1]
Hermannia pinnata. *Lin. ſpec.* 943. *hort. cliff.* 342. *Mill. dict. n.* 6.
[H. verticillata. *Berg. cap.* 169.
Leaves three-parted pinnatifid.

3. Mahernia inciſa. *Cut-leaved Mahernia.*
Curt. magaz. 353.
Leaves lanceolate goſhed.

DESCRIPTIONS, *&c.*

1. Stem ſhrubby, diffuſed; with filiform branches. Leaves frequently from eight to ten in a whorl, ſcarcely divided or pinnatifid. Manner of fructification the ſame as in Hermannia, terminating, with the pedunculs commonly two-flowered. Corolla yellow. Take away the nectarics from the petals, and add them to the ſtamens, and you will have a Hermannia, though a ſtrange one, with the leaves in whorls[2].

Juſſieu remarks, that the claws of the petals are not

[1] Marſhall [2] Hort. kew.

[1] Linn. mant.

con-

convoluted; the filaments flat and narrow below, dilated and obconiate above, with the tip contracted: one ſtyle and ſtigma, or perhaps rather five very cloſely cohering. The reſt as in Hermannia.

Native of the Cape of Good Hope.]

2. This riſes with a ſhrubby ſtem near three feet high, ſending out many ſlender delicate branches, covered with a reddiſh bark. The flowers come out from the ſide of the branches in ſmall cluſters, [they are of a lively red, when they firſt open, and hang down like little bells, commonly two together; appearing from june to auguſt and ſeptember.—Native of the Cape of Good Hope. Introduced in 1774, by Mr. Francis Maſſon. Linnæus regarded it at firſt as a ſpecies of Hermannia, to which genus it is very nearly allied.

3. In point of fize and mode of growth this beautiful ſpecies comes near to the preceding, but differs eſſentially in the ſingular liſtipidity of its ſtalks, the form of its leaves, and the colour of its flowers.

The ſtalks to the naked eye diſcover a manifeſt roughneſs; within a magnifying glaſs it appears that they are beſet on every ſide with little protuberances, whence iſſue tufts of pellucid hairs, and here and there a ſingle hair is diſcoverable with a ſmall red viſcid globule at its extremity: a portion of the ſtalk, when highly magnified, ſomewhat reſembles that of the creeping Cereus. The leaves, which are not ſo manifeſtly hairy as the ſtalk and calyxes, are deeply jagged on the edges, and ſomewhat reſemble thoſe of Pelargonium tricolor. The flowers when in bud are of the richeſt crimſon: as they open they incline to a deep orange, and finally become yellowiſh.

Native of the Cape of Good Hope. It flowered in Mr. Colvill's nurſery in 1796.

The name Mahernia, by which this genus is diſtinguiſhed, is ſaid to be an anagrammatic inverſion of Hermannia; the two genera being very nearly allied, or rather in reality ſcarce to be ſeparated.

PROPAGATION AND CULTURE.

They may be increaſed by cuttings.

Stewartia corchoroides. *Forſt. ſpec. aſp. urab. p.* 126. *n.* 98.
Sida ſpinoſa. *Vahl. ſymb.* 2. *p.* 78.
Leaves villoſe.

DESCRIPTION, &c.

1. Stem arboreſcent, branchy, a fathom or more in height. Leaves alternate, ovate-acuminate, with diſtant ſerratures, and a ſingle branching nerve: they are pubeſcent while young, and afterwards ſmooth: the foot-ſtalks are ſcarce an inch long, and are cylindrical beneath, and afterwards channelled with ſmall membranes, and ſomewhat villoſe: there are no ſtipules: the flowers are large, axillary, and ſubſeſſile: the calyx villoſe externally, and ſmooth internally: the corolla is two inches long, yellow or whitiſh, villoſe externally: the claws of the petals ſomewhat feathery.

2. The ſtem is ſhrubby, and a foot and half in height: the leaves ovate, ſerrate, and villoſe underneath: the flowers ſmall and yellow: the capſules five, ſeparate, and two-horned.

Heads pedunculed five-leaved many-flowered, leaves palmate.
3. Malachra bracteata.
Cavanill. diſſ. p. 98. *n.* 168.
Leaves palmate, heads many-flowered, flowers very ſmall and bracteated.
4. Malachra faſciata.
Jacqu. ic. rar. 548.
With ſerrate three-lobed leaves, the loweſt five-lobed, the common involucres three-leaved and about five-flowered.

5. Malachra

[*] Hort. Kew. [†] Curtis.

5. Malachra alcæifolia.
Jacqu. ic. rar. 549.
With five-lobed leaves cordate at the base; the common involucre five-leaved, and about ten-flowered.

DESCRIPTIONS, &c.

1. Stem thick, erect, two feet high, rough, as is the whole plant; leaves foot-ſtalked, heart-ſhaped; ſtipules four or ſix, ſubulate. Flowers aggregate, pedunculed; peduncles common, two, axillary, placed here and there; each flower ſeſſile. Calyx common, of three ſubtriangular-auriculated leaflets, which are ſtiff and ſharp. Calyx proper ſingle, one-leaved, half-five-cleft, with the diviſions fanced, briſtly at tip, with white briſtles. Corolla yellow, ſpreading, petals roundiſh.

Native of marſhy places in the Caribbee iſlands.

2. Stem tender, round, whitiſh-green, coated with rufous pungent hairs; as is likewiſe the whole plant, which is branchy and taller than a man. Leaves commonly divided into five lobes, which are crenated, hirſute, and bright green. Calyx triple: the common one of five or ſix unequal, oblong, acuminated leaflets, which are toothed, and enlarged below, and very ſhortly foot-ſtalked: the partial exterior one of eight linear leaflets: the interior one-leaved, half-five-cleft. Corolla purpliſh; ſcarce an inch in diameter: tube ſcarlet. Native of marſhy places in Domingo.

3. Stem as well as the whole plant very hairy, the hairs pungent and numerous. Leaves with long foot-ſtalks, heart-ſhaped, roundiſh-palmated, crenated, with ſeven deep acuminated lobes. Stipules capillary, villoſe. Flowers about fourteen on the tip of the peduncle, which is ſolitary and axillary. Each flower is ſhortly pedicelled, and almoſt always ornamented with a leafy bractæ, which is roundiſh, but acuminated. Calyx triple. Corolla ſcarce larger than the calyx, whitiſh, marked in the bottom with red ſtreaks.

Native of America. Cavanilles ſaw only one ſpecimen in the collection of Juſſieu.

4. This has a ſingle upright ſtem of ſix feet in height, and twice the thickneſs of the thumb: it emits branches from the bottoms of almoſt all the leaves, and is thickly beſet with pungent villi. From the right ſide of the boſom of all the branches which proceed from the ſtem a green ſmooth upright ſaſcia aſcends towards the next branch, and is commonly about two lines broad. The leaves are on long foot-ſtalks, and are ſerrated and veiny, roughiſh at the edges; the lower ones roundiſh, and five-lobed at the margin: the upper ones three-lobed, and longer and ſharper. The heads of flowers are axillary: the flowers ſmall, roſe-coloured outward, within whitiſh, with purple ſtreaks. Native of America.

5. Stem ſingle, ſix feet high, upright, an inch thick, green, branching from the axils of the leaves, and covered with glittering pungent hairs: leaves alternate, cordated at the baſe, roundiſh, veiny, very ſpreading, obtuſely ſerrate-crenated. Flowers headed, two or three together, axillary, rather ſmall in proportion to the plant, and of a deep yellow: the flower is ſeated, as in Turnera ulmifolia, at the baſe of each leaflet of the common calyx. Native of Martinico.

MALAMIRI. See *Piper*.

MALAN-KUA. See *Kæmpferia*.
MALAXIS. (*From μαλασσω or μαλαττω, to ſoften.*)
Soland. *Linnæa. prodr.* 119. *Schreb. gen. n.* 1370.
Claſſ. and Ord. 20. 1. Gynandria Diandria.
Nat. order of *Orchideæ*.

GENERIC CHARACTER.

CAL. *Spathes* none. *Perianth* none.
COR. *Petals* five: *three outer*, of which two upper, one lower, lanceolate, blunt, ſpreading: *two inner* linear, acute, reflex about the germ.
Nectary in the middle of the corolla, leſs than the petals, concave, with convex margins, cordate, acuminate behind, bifid in front.
STAM. *Anthers* two ovate, ſcarcely pedicelled, inſerted into the pitcher of the piſtil at the edge, ſitting on two little excavations at the bottom.
PIST. *Germ* pedicelled, ſomewhat cylindric, inferior. *Style*, a pitcher in the middle of the nectary, halved, very ſhort, ſpreading, bearing the ſtamens on its hinder margin. *Stigma* bifoce the little excavations, near the anthers.
PER. *Capſule* pedicelled, oblong, three-keeled, one-celled, opening under the keels, cohering at top and bottom.
SEEDS extremely minute.

ESSENTIAL CHARACTER.

Nectary one-leafed, concave, cordate, acuminate backwards, bifid in front, cheriſhing the genitals in the middle.

SPECIES.

Leaves ovate crenate ſmooth above.
[2. Malope parviflora.
L'Herit. ſtirp. nov. 5. 105. *t.* 50.
Calyxes ſimple, leaves ſubcordate ovate, peduncles ſcarcely longer than the petiole.]

DESCRIPTIONS, &c.

1. The whole plant has greatly the appearance of Mallow, but differs from it in having the cells collected into a button, ſomewhat like a Blackberry. The branches ſpread, and lie almoſt flat upon the ground, extending a foot or more each way. The flowers are produced ſingly upon long axillary peduncles; they are in ſhape and colour like thoſe of Mallow.

[Native of the meadows of Tuſcany and of Barbary. Cultivated by Mr. Miller in 1759.

2. Plant a ſpan high. Root annual. Stem very much branched, ſpreading, red, ſubvilloſe, a foot high. Branchlets alternate, round, green, ſubflexuoſe. Leaves alternate, petioled, ſubcordate or ovate, the lower ones ſubtrilobate, toothed, blunniſh, moſtly five-nerved, nerves prominent underneath, ſcored above, almoſt naked, bright green, ſcarcely paler underneath, ſpreading, one inch long, ten lines wide. Petioles round, ſubvilloſe, a little ſhorter than the leaves. Stipules awl-ſhaped, erect, minute. Flowers axillary, pedunculed, ſolitary, ſeldom two together, a few terminating, purple, three lines wide. Peduncles upright, round, jointed at top, ſubvilloſe. Calyx one-leafed, bell-ſhaped, cloven beyond the middle, ſubvilloſe; diviſions lanceolate, acute. Corolla hemiſpherical: petals cuneate-roundiſh, clawed, oblique at the tip, emarginate, concave, contorted, imbricate on one ſide, the length of the calyx. Filaments capillary, reflex, ſcarcely ſhorter than the corolla. Anthers one-celled, peltate, red. Germ ſuperior, orbicular, depreſſed, pentagonal, covered with the ſheath of the ſtamens. Styles ten to twelve, filiform, reflex, united at the baſe, red, ſcarcely longer than the ſtamens. Stigmas headed-truncate, ſmall, red. Arils ſeveral, kidney-form, collected into a hemiſpherical head, without order, about a receptacle terminated by a filiform axis, covered by the converging calyx, valveleſs, brown. One ſeed to each aril, kidney-form, brown, ſmall.

Native of Peru, where it was found by Joſ. Dombey.

There are other Peruvian ſpecies with ſimple calyxes, which might therefore conſtitute a diſtinct genus.]

PROPAGATION AND CULTURE.

1. This is propagated by ſeeds, ſown in the place where they are deſigned to remain, for it does not bear tranſplanting well. If theſe ſeeds be ſown upon a warm border in auguſt, the plants will frequently ſtand through the winter, and flower early the following ſeaſon, ſo that good ſeeds may be obtained; but thoſe which are ſown in the ſpring rarely ripen the ſame year in England: and theſe plants being large, are often deſtroyed in winter, unleſs they are ſheltered under a frame. It ſeldom continues longer than two or three years.

[2. Ripens its ſeed if ſown in the ſame manner, in favourable ſeaſons.]

MALPIGHIA. (*So named by Plumier in honour of Marcello Malpighi, Profeſſor of Medicine at Bologna, the famous author of* Anatome Plantarum, 1675 and 1679.)

Lin. gen. n. 572. *Reich. n.* 621. *Schreb. n.* 779. *Plum.* 36. *Juſſ.* 253.

Claſſ 10. 3. Decandria Trigynia.

Nat. order of *Tribillatæ — Malpighiæ*. Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* five-leaved, erect, very ſmall, permanent, converging. There are two melliferous glands, oval and gibbous faſtened to the calycine leaflets on the outſide and at bottom.

COR. *Petals* five, kidney-form, large, plaited, ciliate, ſpreading, concave; with long linear claws.

STAM. *Filaments* ten broadiſh, awl-ſhaped, erect, placed in a cylinder, united below, ſmall. *Anthers* cordate.

PIST. *Germ* roundiſh, very ſmall. *Styles* three, filiform. *Stigmas* blunt.

PER. *Berry* globular, toruloſe, large, one-celled.

SEEDS three, bony, oblong, blunt, angular; with an oblong blunt kernel.

OBS. M. nitida *has only a ſingle ſtyle.*

ESSENTIAL CHARACTER.

Cal. five-leaved, with melliferous pores on the outſide at the baſe. *Pet.* five roundiſh, with claws. *Berry* one-celled, three-ſeeded.

DESCRIPTIONS, &c.

This genus conſiſts of trees and ſhrubs, ſome of them climbing, natives of the Weſt Indies. Leaves ſimple, oppoſite (except in n. 8.) ſome briſtly, the briſtles ſtinging and free at both ends; the petiole in many appeariclced or dilated within at the baſe. Peduncles axillary or terminating, one or many-flowered. Does Caucanthus of Surſinam belong to this genus? It is a ſhrub with oppoſite leaves, reſembling theſe plants in the ſtructure and diſpoſition of the flowers, with an unknown fruit! In M. glabra, two diviſions of the calyx are biglandular, two uniglandular, and one naked. M. nitida has only one ſtyle; and it may be doubted whether it is properly placed here.*]

1. This tree uſually grows to the height of ſixteen or eighteen feet, and we have ſeveral trees in England upwards of ten feet high. [Browne ſays, it is a ſmall ſhrub, which ſeldom riſes above ſix or ſeven feet in height, that it is erect in its growth, and divided into very delicate ſlender branches. According to Sloane however it riſes to about fifteen feet, with ſeveral trunks, covered with a clay-coloured ſmooth bark, and dividing into many ſpreading branches, making a pleaſant round head.] Leaves oppoſite, ſubſeſſile, acute, continuing all the year. Flowers in axillary and terminating bunches for umbels, on pedunckles half an inch long, and about four flowers on each. The pedicels have a ſingle joint. Calyx incurved, with glands as deſcribed above. Petals ſubcordate. Stigmas ſimple, with a little drop[a]. Petals roſe-colour or bright purple. Fruit red, round, the ſize of a Cherry, ſmooth-ſkinned, having one or more furrows on the outſide, and containing within a reddiſh, ſweetiſh, not unpleaſant, copious, juicy pulp; and ſeveral triangular fulcated ſtones, ſo fitted together as to ſeem one round one, with ſeveral furrows on the outſide.

This tree is planted in moſt gardens in the Weſt-Indies, where in a little time after rain they ſeldom miſs having ripe fruit, which is eſteemed pleaſant there[b].]

It grows plentifully in moſt of the iſlands in the Weſt-Indies, but whether it be natural there, or introduced only, is not eaſy to determine; for birds, being fond of the fruit, diſperſe the trees every where in great abundance. It uſually flowers here in march and april, but theſe flowers are ſeldom ſucceeded by fruit: it flowers again in july, and when the ſeaſon is warm, fruit is often produced from theſe flowers; the plants being then removed into the open air. [In the Kew catalogue it is ſaid to flower from december to march; and to have been cultivated by Mr. Miller in 1757[c].]

2. This riſes with a ſhrubby ſtalk ten or twelve feet high, dividing into ſeveral ſlender ſpreading branches, covered with a light brown bark. The flowers are produced in ſmall umbels at the end of the branches, upon ſhort pedunckles. Corolla pale roſe-colour. Berry roundiſh, pulpy, with ſeveral furrows, red when ripe, including three or four hard angular ſeeds. [It is of the ſame ſize and make with our common Engliſh Cherries, very ſucculent, and of a pleaſant ſubacid taſte. This ſhrub has much the appearance of the Pomegranate, is full of ſlender flexile branches, and ſeldom riſes above ſeven or eight feet[d].

Native of the Weſt Indies. Browne ſays it had been but lately introduced into Jamaica.—It was introduced here in 1690, by Mr. Bentinck[e].

3. This is a ſhrub, a fathom in height. Stem upright round even; branches deciuſſated upright round, covered with a ſtriated bark. Leaves deciuſſated-oppoſite, oblong, blunt, with a convex margin, nerved, veined, ſtriat, pale green, ſhining; on ſhort petioles. Racemes axillary, ſhorter than the leaves, many-flowered; flowers pedunckled, the ſame ſize as in M. glabra, yellow. Berry three-lobed, three-ſeeded, blood-red[f].

Browne ſays, it ſeldom riſes above three feet in height, but ſurrows out many ſlender upright branches, and bears large hard berries, which are much eaten by turkeys and other large fowls.

According to Jacquin, the leaves are four inches long, ending in a blunt point; there is only a ſingle ſtyle, (perhaps the three were glued together ſo as to appear one) and the ſeeds are ſmooth, commonly two in a berry.]

Mr. Miller ſays, his *nitida* is ten feet high, the ſtem covered with a light brown ſpotted bark; the flowers come out from the ſide of the ſtalks in ſmall umbels, ſtanding erect, on pedunckles ſcarcely an inch long; the corolla is of a pale bluſh colour; the berries are roundiſh and ſurrowed, covered with a red ſkin, and contain three hard angular ſeeds.

[Native of the Weſt-Indies. Common in Jamaica; about Carthagena in New Spain, where it was found by Houſtoun, and ſent to Miller; who therefore cultivated it before 1733[g].

4, 5. Natives of the Weſt-Indies[h].

6. This ſhrub riſes with a ſtrong upright ſtem about three feet high, covered with a brown bark, ſending out ſeveral ſide branches which grow erect. Leaves ending in acute points, ſeſſile, covered with fine briſtles, which do not appear unleſs cloſely viewed[i]; theſe briſtles are double pointed, and ſuſtained by pedicels of the ſame fragile tranſparent ſubſtance with themſelves, deſcending from the middle of them; theſe are eaſily broken, but the briſtles enter pretty deep in, and ſtick cloſe to whatever has forced them on[k]. The flowers come out upon long ſlender peduncles from the axils at each joint, four, five or ſix together, in a ſort of whorl. The three ſtyles ſtand apart. It flowers in july and auguſt (to october), but has not perfected ſeeds in England.

It is very different from Plumier's M. latifolia, folio ſubtus ſpinoſo (which Linneus gives as a ſynonym of his urens); the leaves of this being more than twice as big, and armed on both ſides with ſtinging briſtles; whereas that has them only on the under ſide. Plumier's plant alſo riſes with a much taller ſtem, and ſeldom flowers here.

The ſeeds of this plant were ſent to Mr. Miller (about 1753) by Monſ. Richard, gardener to the King of France at Trianon, by the name of *Bois de Capitain*[l]. It is called in the Engliſh Weſt-India iſlands *Cowhage Cherry*.

Linneus deſcribes the urens thus in his Species Plantarum. Leaves ovate-oblong, quite entire, ſubpetioled, the ſurface, eſpecially underneath, having ſtiff ſtinging double briſtles ſcattered over it. Stipules on each ſide two. Flowers axillary, on each ſide four, on one-flowered peduncles, which have a joint.]

Mr. Miller deſcribes his urens as having a ſtem from fifteen to eighteen feet high, dividing into many pretty ſtrong branches, which are furrowed, and covered with a brown bark: the leaves are from three to four inches long, and one inch broad at the baſe, where they are rounded in form of a heart, leſſening gradually to a point; covered on the under ſide with ſtinging briſtles, which when faſtened into the fleſh are difficult to get out again. The flowers are produced in umbels from the ſide of the branches; they are of a light purple colour. He had the ſeeds from Jamaica, by Houſtoun, [and therefore muſt have cultivated it before 1733.]

7. This riſes with a ſhrubby ſtalk ſeven or eight feet high, covered with a bright purpliſh bark which is ſpotted and furrowed, dividing towards the top into ſeveral ſmaller branches. Leaves numerous, about two inches long, and a quarter of an inch broad, acuminate, of a lucid green on their upper ſide, but of a ruſſet brown on their under, where they are cloſely armed with ſtinging briſtles. Flowers from the ſide and at the end of the branches in ſmall umbels, ſmall,

[a] Jacq. [b] Linn. mant. [c] Sloane.
[d] Mill. fig. [e] Browne. [f] Hort. kew.
[g] Swartz. [h] Hort. kew. [i] Swartz.
[k] Mill. fig. [l] Browne [m] Mill. fig.

and of a pale purple colour. Fruit ſmall, oval, furrowed, dark purple when ripe.

[Native of the Weſt Indies; Jacquin ſaw it flowering in june in the iſland of St. Martin.] Mr. Miller had it from the iſland of Barbuda. [He cultivated it in 1752[a].

8. This is a tree, with the leaves a hand in length, thick, ſubpetioled, quite entire, pubeſcent above, tomentoſe underneath, commonly alternate. Racemes long, tomentoſe[b].

Browne calls it the larger Locus-berry tree, and ſays that the upper branches terminate in looſe bunches of flowers, each of the diviſions being ſimple, as well as the top of the main ſupporter, which terminates alſo in a ſingle ſpike. The glands of the calyx are remarkably diſtinct in this ſpecies, which ſeems to have all the habit and appearance of Cominia.

Native of the Weſt India iſlands and Guiana.

9. This tree riſes frequently to the height of thirty or forty feet or more. The leaves while young, are covered on both ſides with down, but this falls off gradually, and they appear pretty ſmooth and ſhining after a ſhort time. There is a remarkable ſtipula at the axil of every leaf, which, with its oppoſite, ſeems to embrace the ſtalk. Two of the ſeeds are generally abortive in the berry.

Native of Jamaica, where it is common in the lower hills of Liguanea[b]. Browne calls it the Locus-berry Tree.

10. Native of the Weſt Indies. Cultivated before 1742, by Robert James Lord Petre[a].

Is this the *incana* of Miller, n. 7? He deſcribes it as ariſing with a ſtrong woody ſtalk eighteen or twenty feet high, dividing into many branches, covered with a brown ſpotted bark. Leaves lanceolate, hoary on their under ſide. Flowers in axillary umbels, of a roſe-colour. Fruit oval, channelled. He had it from Mr. Robert Millar, who found it at Campeachy.

[11. Leaves ending in the petioles, a foot long, villoſe, clothed underneath with a very cloſe nap. Racemes long, villoſe.—Native of South America[c].

Sloane's figure, referred to here by Linneus, is Clethra tinifolia of Swartz; the deſcription perhaps may belong to Malpighia craſſifolia[d].]

12. This riſes with a ſhrubby ſtalk to the height of ſeven or eight feet, ſending out branches the whole length, which are covered with a gray bark. Leaves narrow, prickly like thoſe of Holly, and having many ſtinging briſtles on their under ſide. The flowers are produced in ſmall cluſters from the ſide of the branches, ſmall and of a pale bluſh-colour. The fruit is more pointed than the common ſort, and turns to a dark purple colour when ripe.—Dr. Houſtoun found it in plenty in the iſland of Cuba.

[The above is what Miller names M. lucida, the deſcription of which, according to Reichard, belongs to Linneus's M. aquifolia.]

Miller deſcribes M. ilicifolia as having a ſtrong woody ſtem from fifteen to twenty feet high, dividing into many ſpreading branches, covered with a gray bark. Leaves oblong-ovate, of a firm conſiſtence, about an inch long, and half an inch broad, rounded at their ends, of a lucid green. The flowers come out from the ſide, and alſo at the end of the branches, upon pretty long peduncles, which branch in form of a raceme or long bunch. They vary in colour, ſome being of a bright red, others orange in the ſame bunch. Berries ſmall, oval, leſs furrowed, when ripe dark purple. Sent from the iſland of Barbuda.

13. This is a very low ſhrub, ſeldom riſing more than two or three feet high. Stalk thick and woody, as are alſo the branches, which come out on every ſide from the root upwards, and are covered with a rough gray bark. Leaves lucid, half an inch long, and almoſt as much broad, appearing as if cut at their ends, where they are hollowed in, and the two corners riſe like horns, ending in a ſharp thorn, as do alſo the indentures on the ſides. The flowers come out from the ſide of the branches, upon peduncles an inch long, each ſuſtaining one ſmall pale-bluſh flower. Fruit ſmall, conical, furrowed, changing to a purple red colour when ripe.

The fruit of ſeveral of the ſorts are gathered promiſcuouſly and eaten in the Weſt Indies; but the firſt ſort is cultivated for the fruit, which is but indifferent, and much inferior to our European Cherries; having however a pleaſant flavour, it is agreeable to the inhabitants of hot climates.

There are many other ſpecies, not yet ſufficiently aſcertained. [I have added five from Jacquin.

14. This ſmall tree agrees ſo perfectly in habit with M. glabra, that it is diſtinguiſhed from it only by the briſtles on the leaves, and the leſs pleaſant flavour of the fruit; and therefore is diſtinct from M. urens, in the leaves only. This however is by much the moſt prurient of all the prurient ſpecies. All the ſorts of Malpighia have eatable fruits, but glabra and urens only are in common uſe. The latter is inſipid, and eaten only raw by children and ſavages: the former is much eaten boiled with ſugar, but is generally neglected raw. Jacquin however, and two companions, being very thirſty with travelling in the heat in Martinico, took a large quantity of theſe berries without ſuffering from them in any degree.

15. This is an upright ſhrub, eight feet high. Leaves quite entire. Racemes ſimple, two inches long, on two-leaved branchlets. Flowers yellow. Berries red.—Near Carthagena.

16. This alſo is an upright ſhrub, eight feet high. Leaves blunt, quite entire, three inches long. Racemes oppoſite. Flowers ſweet, ſmelling like thoſe of yellow Lupine: petals yellow. Stigma ſometimes trifid, with a three-grooved fruit, containing three ſeeds, convex on one ſide and angular on the other. Berries orange coloured.

Jacquin having examined all the Linnean ſpecies, except craſſifolia, remarks, that the calycine glands are either all free, or ſome coaleſcent in different numbers; that ſome have only one, others three ſtyles, in the latter the ſtigmas being always ſimple, in the former bifid or trifid, with the ſame number of ſeeds, that the berry in a few is ſubtrilobate, but in moſt grooved, containing ſeeds that are either wrinkled or ſmooth.—This ſort grows near Carthagena.

17. This is a ſmall tree, ten feet high, upright and having a handſome head. Leaves quite entire, a foot long. Petals yellow.—Native of Martinico.

18. This is a tree of thirty feet in height and more, with an upright trunk, and a pyramidal elegant head. Leaves broad-lanceolate, three or four inches long, ſharp, petioled. Flowers yellow, ſweet, in long racemes, not unlike thoſe of the Horſe Cheſtnut. Berries yellow, ſoft, ſtarred on both ſides, ſmaller than a Cherry, acid but not pleaſant, and therefore left chiefly to birds. The wood is white. By the natives called *Bois tan*; the bark being fit for tanning leather.—Common in Martinico[e].]

PROPAGATION AND CULTURE.

Theſe plants are preſerved in the gardens of thoſe perſons who are ſo curious in botanical ſtudies, as to erect hot-houſes for maintaining foreign plants: and where there are ſuch conveniencies, theſe plants deſerve a place; becauſe they retain their leaves all the year, and commonly continue flowering from december to the end of march, when they make a fine appearance at a ſeaſon, when there is a ſcarcity of other flowers, and many times they produce ripe fruit here. Thoſe ſorts whoſe leaves are armed with ſtinging briſtles, like the Cowitch, are the leaſt worthy of a place in ſtoves, becauſe they are ſo troubleſome to handle, nor do their flowers make ſo good an appearance as many of the other ſorts. The thirteenth ſort is the moſt valuable for its flowers, which are produced in larger bunches than thoſe of any of the other, and there being flowers of different colours in the ſame bunches, they make a fine variety; and this ſort grows more like a tree than the others, the leaves are alſo of a ſtronger conſiſtence and of a lucid green.

[a] Hort. kew. [b] Linn. ſpec. [c] Browne. [d] Hort. kew. [e] Linn. ſpec. [f] Swartz obſ. 182.

[a] Jacquin. amer. p. 2.

As these plants are natives of the warmeſt parts of America, they will not live through the winter in England, unleſs they are preſerved in a warm ſtove; but when the plants have obtained ſtrength, they may be expoſed in the open air in a warm ſituation, from the middle or latter end of June, till the beginning of October, provided the weather continues ſo long mild; and the plants ſo treated, will flower much better than thoſe which are conſtantly kept in a ſtove.

They are all propagated by ſeeds, which muſt be ſown upon a good hot-bed in the ſpring, and when the plants are fit to tranſplant, they muſt be each put into a ſeparate ſmall pot filled with rich earth, and plunged into a hot-bed of tanners bark, and muſt be treated in the ſame manner as has been directed for other tender plants of the ſame country; and for the two firſt winters, it will be proper to keep them in the bark-bed in the ſtove; but afterwards they may be placed upon ſtands in the dry ſtove in winter, where they may be kept in a temperate warmth, in which they will thrive much better than in a greater heat; theſe muſt be watered two or three times a week, when they are placed in the dry ſtove, but it muſt not be given to them in large quantities.

Stem upright, leaves palmate toothed, corollas fmaller than the calyx.

DESCRIPTIONS, &c.

1. Stem pale green, two or three feet high, branched. Leaves almoft round, an inch and quarter long, and three quarters of an inch broad at the bafe, pale green, fmooth, on petioles three quarters of an inch in

in length. The tops of the twigs and branches, for the length of an inch, are thick set in a ſpike with orange-coloured flowers, in very hirſute calyxes.

Native of Jamaica, in cleared, barren, rocky lands[1]. Cultivated by Mr. Miller in 1726. It flowers in ſeptember and october[2].

2. Stem ſhrubby, tomentoſe, or hiſpid, two feet high, upright, round, little-branched. Leaves ovate, ſubacute, ſubcordate, curled. Outer calyx three-leaved, inner five-toothed. Petals ſhort. Stamens five. Styles many. Beaks of the ſeeds, when the flower is fallen, very ſhort, forming the angles of a retuſe fruit[3].

Native of the Eaſt Indies and Cochinchina.

3. This is ſiſter plant to M. coromandeliana, but ſtiffer. Leaves ſerrate, ſtrigoſe. Stipules linear. Flowers at the tops of the branches, yellow. Seeds in a retuſe diſk, without awns, the upper margin crenulated with minute tubercles.

Native of India[4].

4. Stem a foot high, round, hiſpid. Branches leafy, round, hiſpid. Leaves alternate, oblong ſometimes cordate at the baſe, obtuſe, hiſpid. Petioles round, longer, hiſpid. Pedunicles ſolitary, upright, ſhorter than the petiole; flowers terminating, in a ſort of ſpike, ſeſſile, yellow. Leaflets of the outer calyx linear. Styles ten to ſixteen. Fruit hirſute: with two cups of the anis in a pair, the third ſuperior.

Common in Jamaica, among graſs[5]. Theſe are both annual plants.

5. This is a ſhrub, a fathom in height. Stem upright, round, ſmoothiſh, very much branched. Branches alternate, almoſt upright, root-like, ſomewhat rugged, tomentoſe, twigs hoary. Leaves alternate, ſpreading or hanging down a little, ſubcordate, acute, entire at the baſe, lonſely nerved with the nerves prominent underneath, ſubtomentoſe, ſomewhat rugged, pale green, two inches and a half or three inches in length, from an inch and half to two inches and a half in breadth. Petioles ſhorter by half than the leaf, ſpreading very much, round, tomentoſe. Stipules awl-ſhaped, caducous. Flowers aggregate or ſolitary, the upper ones in a ſort of ſpike, on ſhort pedunicles, yellow marked with red ſpots on both ſides, half an inch over. Pedunicles tomentoſe, whitiſh. Calyx ſubtomentoſe; leaflets of the outer awl-ſhaped, preſſed cloſe; inner bell-ſhaped, longer; ſegments lanceolate, acute, ſpreading. Germ pubeſcent. Arils or capſules from ten to twelve, obſoletely kidney-form, acuminate, two-horned, ſcarcely opening inwards, pubeſcent, aſh-coloured. Seeds brown.

Native of Peru, about Lima; where it was found by Dombey, and ſent to the Paris garden. It flowers in its native ſoil in july and auguſt. Though ſhrubby, it ſeldom comes to a ſecond year, but perfects ſeeds here, and readily grows from them. The Spaniards in America call it *Eſcoba zimarrona*, or wild Broom; the inhabitants making common brooms of the branches[6].

Introduced in 1782, by Monſ Thouin. It flowers in auguſt and ſeptember[7].

6. Stem ſubfruticoſe, round, branched, three feet high, covered with numerous ſtellate hairs, ſo ſmall and cloſe that this and the whole plant appear mealy. Leaves alternate, ſeveral times longer than the petioles, crenate, the lower ones often four inches long, and an inch wide; the upper ones ſhorter and narrower. Stipules briſtle-ſhaped. Flowers numerous and as it were glomerate, with ſeveral ſhort, one or two-flowered pedunicles; on the top of the ſtem and branchlets not ſo numerous, but at length in pairs and then ſolitary. The outer calyx conſiſts of three very ſmall briſtles: the inner is half-five-cleft. Corolla pale violet; petals ſpreading, emarginate. Tube of the ſtaments ſhort, hairy at the baſe, ſurrounding the germ, reſembling the tube of Sida. Anthers violet. Fruit ſpherical, umbilicate, tomentoſe. Capſules awn-leſs, three-ſeeded. Seeds black, ſmooth.

Native of Mexico[8]. Introduced in 1780, by Benjamin Bewick, Eſq. It flowers in auguſt[9].

[1] Sloane. [2] Hort. kew. [3] Linn. ſpec. and Loureiro. [4] Linn. ſpec. [5] Swartz. [6] L'Heritier. [7] Hort. kew. [8] Cavanilles. [9] Hort. kew.

7. Root annual. Stem a foot high, ſtiff, round, ſomewhat hairy: branches few, ſhort, upright, from the lower axils. Leaves ſcarcely tomentoſe. Pedunicles axillary, upright, ſolitary, one-flowered. Spike terminating, with many ſeſſile flowers, expanding after noon. Corolla yellow. Outer calyx linear, ſpreading, the length of the inner; which is urceolate at the baſe. Styles ten, longer than the ſtamens[1].

Native of North America. Cultivated in 1759, by Mr. Miller. It flowers in june and july[2].

8. This alſo is an annual plant. Stem from two to three feet high, with hairs thinly ſcattered over it, uſually in pairs. Leaves ſeven-lobed, plaited, ſmooth, veined, ſharply ſerrate; on petioles the length of the leaf. Stipules ovate-lanceolate. Pedunicles long, naked. Spike directed to one ſide, turned upwards, recurved before the flowers open. Corollas ſmall, purple. Seeds ten, roughened above with many alternate teeth[3].

According to Jacquin, the leaves are five or three-lobed; and the flowers red.] Miller ſays, that the leaves are broad, hairy and three-lobed; the flowers ſmall, pale blue, and ſet very cloſely on the ſpikes, appearing in june. It grows naturally in Peru, whence the ſeeds were ſent to the Royal garden at Paris by Monſ. Joſeph de Juſſieu. [It was cultivated by Mr. Miller in 1759[4].

9. This is ſiſter to M. peruviana, but the flowers are blue, not purple[5]. According to Jacquin, the leaves are ſeven-lobed.

Native of Peru, about Lima. It is an annual plant, and flowers in july. Introduced in 1768, by Monſ. Richard[6].

10. This plant is handſomely echinated on the diſk of the leaf, and is a native of Spain[7].] Mr. Miller deſcribes it as having a ſhrubby woolly ſtalk, four or five feet high, ſending out branches on every ſide, with woolly, rough leaves. Pedunicles axillary, ſupporting four or five flowers, bright purple, ſhaped like thoſe of the common Mallow: they appear in july, and the ſeeds ripen in autumn. It ſeldom continues more than two or three years.

[In the Kew catalogue it is ſaid to be a native of the Cape of Good Hope, and to have been introduced by Maſſon in 1774.

11. This was introduced in 1780, by Benjamin Bewick, Eſq. is ſhrubby, and flowers in january and february. Its native place is unknown[8].

12. Stem a fathom in height, round; the tender branches tomentoſe, but becoming ſmooth by age. Leaves alternate, longer than the tomentoſe petioles, the lower lobes ſhorter, the middle longer. Stipules lanceolate, reflex. Flowers axillary, ſomewhat branched; branchlets ſhort. Outer calyx of three, ſometimes two briſtles, one of which is inferior: inner calyx five-cornered, with prominent angles, half-five-parted; divitions ovate-acute. Corolla white, a little larger than the calyx; petals orbiculate, with very narrow claws. Tube of the ſtamens very ſhort: anthers whitiſh. Style divided into twelve or fourteen whitiſh ſegments.

Found near Mexico. It flowers in the Royal garden at Madrid in december.

13. Stem ſhrubby, round, two feet high, tomentoſe eſpecially when tender. Leaves alternate, nearly equal to the petioles, the breadth almoſt equal to the length, the middle lobe more produced, crenate, ſubtomentoſe underneath, the nerves and petiole very tomentoſe. Stipules lanceolate, ſhrivelling. Umbels five-flowered or thereabouts: common pedunicle axillary, ſolitary, erect, elongated, having a few ovate ſhrivelling ſcales on it: rays about an inch long, thick. Outer calyx of three, ſometimes four orbicular concave leaflets, dark purple, falling off before the corolla: inner globular at the baſe, five-cornered above, half-five-cleft; diviſions acute, tomentoſe. Corolla bell-ſhaped, twice as large as the calyx, very deeply divided into five rounded ſtriated ſegments of a fiery-violet colour,

[1] Linn. ſpec. [2] Hort. kew. [3] Linn. ſpec. [4] Hort. kew. [5] Linn. ſpec. [6] Hort. kew. [7] Linn. ſpec. [8] Hort. kew.

with the base by which they are united white. Tube of the stamens whitish, a little shorter than the corolla, thick, upright. Germ superior, tomentose, of an oblate spheroidal form, with as many grooves as there are stigmas. Style purple-rose coloured, hollow, entire at the base, dividing into from fifty to sixty threads. Fruit globular, umbilicated. Seeds three in a capsule. It differs from its congeners in the outer calyx being deciduous. In the manner of flowering it approaches to Dombeya; in fruit to Sida. It is therefore between Malva and Sida.

Native of Mexico: flowering from january to march at Madrid [1].]

14. This rises with a woody stalk ten or twelve feet high, sending out branches from the side the whole length: the stalks and branches are closely covered with hairs. Leaves hairy, indented on their sides, so as to have the appearance of a trilobate leaf: these on the young plants are three inches long and two broad at their base; but as the plants grow older, they are scarcely half that size. The flowers come out from the side of the branches, upon peduncles an inch long; they are of a deep red colour, shaped like those of the common Mallow, but smaller. It flowers great part of the year.

[Dillenius, who distinguishes the three varieties here given, as species, describes the first, as having the stem from eighteen inches to three feet in height, and higher, when more advanced, not much branched: the stems round and woody, not very thick, scarcely so large as the little finger, the bark ash-coloured below, bay at top; the ends of the twigs green. Leaves not unlike those of the Gooseberry, with several smaller ones from the same point, smooth, paler underneath. Peduncles axillary, solitary, slender, perpendicular to the stem. Calyx smooth; outer usually three-leaved; inner divided almost to the base into five broadish segments. Capsules hirsute: twelve in a whorl, muticate with four tubercles arched upwards and spreading on each side at the back, of a brown bay colour, they are broader than they are high, compressed and coriaceous. Seed rounded-beaked, less-shaped, smooth, bay-coloured [2].

Native of the Cape of Good Hope. The first mention of this shrub is by Peines in hort. bof. 1705 and 1713. In 1713 it was cultivated in the botanic garden at Chelsea [3]. Dillenius was the first who described and figured it [4].

β. This has thicker, higher stems, of a brownish red colour. Leaves hirsute, broader, with wider segments less deeply cut, but with the toothlets sharper and serrate. The outer calyx has somewhat larger segments; the inner is subhirsute. Peduncles jointed, and bent a little downwards; whereas in the preceding they are short and not jointed [5].

The whorls of fruit are a little larger than in the preceding, and not muricated. Capsules compressed, horizontally oblong, with waved wrinkles running from the centre towards the circumference, of a dirty black colour [6].

γ. The rugged Cape Mallow differs from the others in having the hairs of the leaves and stem simple not compound; the flowers almost upright not drooping [7].

It is a lottier and stouter plant, with larger flowers, having deeper and darker spots on the petals, the calyxes more hirsute, with the outer leaflets larger, and the peduncles shorter, without any joint; the leaves also are thicker, more wrinkled, softer, broader, less gashed, not so like those of the Gooseberry, with the toothlets less sharp [8].

The fruit has twelve capsules in a whorl, rounded-kidney-form, somewhat compressed, brittle, black: back rounded, rugged, but neither tubercled nor muricate: sides flat, obsoletely striated. Seed kidney-form, with a depressed streak on the back, bay-coloured. The embryo in this is white; in the two others green [9].

Gærtner can scarce think this a variety of M. capensis. On the contrary Miller, who is very apt to advance varieties into species, says that] the leaves of this appear very different from either of the other, being deeply divided into three lobes, which are also deeply indented, so that any person would suppose it to be a different species; but this he has frequently raised them all, with other intermediate varieties, from the seeds of one plant.

[15. Trunk very small, branching almost immediately from the root: branches six feet and a half long, about the thickness of a wheat straw at the base, rough with fasciculated hairs, dividing into smaller branches. Leaves narrow at the base, entire, oblong, cuneiform, an inch or more in length, most of them divided into three deep incisures: divisions sharply crenated, rugose and plaited, smooth above, rough below: stipules two, semilunar, spreading. Flowers axillary, in the lower branches solitary, in the upper ones bimate, peduncled, bending. Corolla purple, streaked, with deep-purple or red spots at the base.

16. This is a shrub about four feet high, upright, but so weak, that unless it is supported, half the trunk and the branches hang downwards. Trunk thicker than a quill, round, with a brown bark, rugged with scars from the fallen leaves and stipules. Younger branches villose and glutinous. Leaves acute, alternate, petioled, somewhat rugged, villose, dark green on the upper surface. Stipule on each side the petiole, ovate, acute, entire, somewhat convex. Peduncles axillary, solitary, one-flowered, villose. The three leaflets of the outer calyx are ovate, acuminate, somewhat villose: inner half-five-cleft, with divisions similar to the leaflets of the other. Petals pale rose colour, spreading very much, twice as long as the calyx, streaked with red at bottom. Column of filaments white and hirsute. Antners and stigmas purple. Anthers about twelve, black, somewhat wrinkled and ruggedl. Seeds smooth, brownish. Named from the highly balsamic smell of the plant. Jacquin had the seeds from Holland about the year 1777. The native country is unknown [4]. Probably from the Cape of Good Hope.

17. This is a shrub very much resembling M. capensis, but the whole of it, except the upper surface of the leaves is hoary or subtomentose. Leaves small, cordate, three or five-lobed, lobes gashed, the middle one more lengthened out. Flowers large, in terminating racemes. Outer calyx lanceolate. Corolla white. Fruit globular, rostrate, with from fifteen to twenty cells, closely connected, as in the Abutilon of old authors.

Native of the Cape of Good Hope [5].

Linnæus, in his Species Plantarum, p. 971. has 3 species under the name of M. abutiloides, totally different from this, which was omitted in the thirteenth edition of Systema vegetabilium, and ought to be restored [6]. It is an American plant, native of Providence in the Bahama islands; and figured by Dillenius under the name of Abutilon alcheringes, flore carneo, fructu globoso, t. 155. f. 1. It has the appearance of an Althea, is tall, and is distinguished from the other Mallows by its subglobular, striated pericarps, with many-seeded cells, not at all distinct on the outside. The stem is upright; the leaves are lobed and villose; the calyxes very short [7]. Catesby brought over the seeds, and it was cultivated in the Fulham garden in 1725, but did not flower there till july 1732 [8].

18. Root annual. Stems creeping, eighteen inches and longer, round, putting out roots at the lower joints, hairy. Leaves villose, soft, those next the root larger, roundish, pale-ferrate, smaller and more deeply divided as they ascend, five-lobed and seven-lobed, all on long hairy petioles, gashed and ferrate on the edge. Flowers axillary and terminating, on almost upright peduncles from an inch to an inch and half in length, small, the colour of Burgundy wine, the claws of a darker red. Seeds in each capsule commonly two, small, smooth, one of them commonly abortive. Capsules small, a little hairy at top, with two short horns on the outer margin, they are bind and open from the

top to the middle, but at the lower and inner part they remain entire [a].

Native of Carolina, whence the ſeeds were brought by Catesby. It was cultivated in the botanic garden at Chelſea in 1723 [b].

19. This is an annual plant, differing from M. rotundifolia in having the ſtem almoſt upright, and three times as large; the leaves more acute, with the tip of the petiole aſcending; the calyxes ſmooth, the outer linear not lanceolate; the flowers ſeſſile; the calyxes, when the fruit is ripe, purple; the awns wrinkled above and toothed on the ſides.

Native of Barbary [c].

20. Root annual. Stems decumbent, ſcarcely branched, green, ſomewhat ſtriated. Leaves on long petioles, five-lobed; lobes rounded on the lower leaves, in the reſt lanceolate, crenate, with a lanceolate ſtipule at the baſe of the petioles. Flowers axillary, commonly four, on erect naked almoſt equal peduncles, half an inch long. Calyx converging. Corolla pale red, a little larger than the calyx; petals emarginate. Stems, petioles, peduncles and calyx bearded with longiſh hairs. Leaves very finely and evenly birſute. It differs from rotundifolia in having the leaves acutely lobed not crenate, in the colour and ſize of the flower, and in the peduncles, which in rotundifolia are unequal, and ſometimes leafy. In parviflora, beſides the ſame difference of the leaves, the calyx is ſpreading and ſmooth, the flowers conglomerate in the axils not ſcattered [d]. Vahl doubts whether it be really different from M. parviflora, to which it is certainly very nearly allied.

Found by Bellardi in the county of Nice.

21. Root annual, or perhaps biennial. Chiefly diſtinguiſhable from M. rotundifolia to which it is very nearly allied, in the petals ſcarcely exceeding the calyx, and the flowers being never more than two in each axil. After all it is doubtful whether it be permanently diſtinct from the next ſpecies [e], and indeed this with the two preceding ones require farther examination, before it be finally determined whether they are ſpecies or only varieties. Hudſon took it for the parviflora of Linnæus; but being different from that, which has the leaves very angular and ſharply ſerrated, the flowers ſeſſile or nearly ſo, three or four together in axillary cluſters, it was neceſſary to give it another name.

It was firſt found by Mr. James Sherard in company with Mr. Rand, at Hithe in Kent. Mr. Hudſon remarked it in the ſame place. Dr. Withering ſays, that his ſpecimens were gathered in Pembrokeſhire. In Ray's ſynopſis it is obſerved, that it differs from the other Mallows in having the ſeeds wrinkled.

22. Root annual, whitiſh, ſtriking deep. Stems ſeveral, branched, lying cloſe to the ground, except the flowering branches, which aſcend a little, not creeping or putting out roots from the joints, from nine to twelve inches in length or more. (I have ſpecimens before me, on Sept. 16th, 1797, four feet long,) round, pubeſcent, frequently tinged with purple on one ſide. Leaves covered on both ſides with a fine down, ſomewhat rugged, roundiſh kidney-form or almoſt orbicular, cordate or hollowed at the baſe, the ſurface waved or raiſed a little at the angles between the lobes, and when the leaves, eſpecially the larger, are laid flat, ſo as to preſs out theſe wavings, hardly any interval remains between the two edges at the baſe, ſo that they then are almoſt round, allowance being made for the lobes, which are very ſhallow, five or ſeven in number, rounded, ſerrate or rather crenate on the edge, having five or ſeven ribs on the under ſide, not flat but concave upwards, or what Linnæus calls cucullate, eſpecially the younger ones; the largeſt two inches and a half or three quarters across, and an inch and a half from the petiole to the apex. There is a dark purple ſpot at the corner of the baſe or top of the petiole, which is alſo tinged with purple, roundiſh but with a ſlight channel along the upper ſide, hairy and ſlightly rugged, four or five inches in length. Stipules in pairs, lanceolate, fringed with hairs. Peduncles axillary, ſhorter than the petioles, frequently two together, but often more of different lengths, ſometimes one only, the other ſeeming to have proved abortive; they are round, pubeſcent and one-flowered. Leaves of the outer calyx linear, bluntiſh, nearly as long as the inner; which is bell-ſhaped, pubeſcent with a ſlight ruggedneſs, of a paler yellow; ſegments ovate, acute, keeled, toothletted and ſlightly waved. Corolla white with purple veins, and purple towards the top, (at leaſt it is ſo in my ſpecimens). Lightfoot ſays, white ſtreaked with red veins. Curtis, white, ſtriped with reddiſh veins. Withering, purpliſh roſe red, ſometimes paler. The veins are darker, and more inclined to red than the purple at the end, which in my ſpecimens cannot be called red, but beautiful pale lilac purple. Linnæus ſays, that about Upſala it is entirely white. The corolla is full twice as long as the calyx: petals narrow-wedge-ſhaped, very blunt and deeply emarginate at top, nearly upright and ſubſeſſile. Filaments and anthers white. Styles twelve to fourteen, purple, hairy on one ſide. Fruit three-eighths of an inch in diameter, made up of as many capſules as there are ſtigmas [f].

Native of moſt parts of Europe, on dry banks, by way ſides, under walls and other fences, flowering from june to ſeptember.

23. Peduncles in flowering time bowing, ſhorter than the leaves. Petals red, rounded with a point. Capſules more than five, in a ring, or ſcattered.

Native of Bithynia. Arduini. It is perennial [g]. I obſerve that the fruiting peduncles are frequently arched upwards in M. rotundifolia.

24. Root perennial, (or biennial, according to ſome; annual according to others,) whitiſh, the thickneſs of a finger, ſtriking deep, thinly furniſhed with large fibres, not creeping, ſweetiſh and viſcid. Stem more or leſs upright, according to circumſtances; in hedges drawing up to the height of ſeveral feet, but by foot-paths and among rubbiſh in a manner proſtrate, from one to three feet in length or more, round, inclined to be woody, hairy, branched. Leaves five-lobed, (rarely ſix or ſeven,) unequally crenate, hairy on both ſides, or only underneath, the ſurface waved and concave upwards, eſpecially the younger ones, having a dark purple ſtain at the inſertion of the petiole: root-leaves five or ſix inches in diameter, on petioles eighteen inches long; ſtem-leaves three or four inches in diameter, darker green and more deeply lobed than in M. rotundifolia. Petioles three-cornered, hairy. Stipules two at the baſe of each petiole, ovate, acuminate, ciliate. Peduncles axillary, nearly cylindrical, ſeveral together, forming a ſort of umbel, one-flowered, hairy, an inch long. Leaflets of the outer calyx lanceolate; ſegments of the inner broader; both hairy without, ſmooth within, toothed at the edges, and the teeth terminating in long hairs. Petals deeply emarginate, purple with three or four darker or red ſtreaks, varying ſometimes to white, or with more or leſs of a blueiſh caſt. Filaments and ſtyles purple or red [h]. Capſules about ten, or from ten to fifteen, rounded-kidney-form, three-ſided, ſomewhat cruſtaceous, brittle, cloſe all round, dark ſtraw-colour, excavated wrinkled on the back, ſtreaked in curves on the ſides. Seeds kidney-form, three-ſided, dotted, whitiſh, aſh-coloured [i].

Common in moſt parts of Europe, by hedges, roads, and in waſte places, flowering from june to ſeptember. In the north of England it is called *Mauls*. In French, *Mauve, la grande Mauve*. In German, *die wilde Malve*. In Dutch. *Wilde Malwe*. In Daniſh, *Den ſtore katoſt*. In Swediſh, *Kattoſt*. In Italian, *Malvone*. In Spaniſh and Portugueze, *Malva ſylveſtre*. In Ruſſian, *Proſkurat*.

Cattle do not appear to be fond of it. Every part of the plant, particularly the root, abounds with a mild mucilage. The root boiled is much uſed as an emollient cataplaſm; and an infuſion of it is generally preſcribed in all caſes wherein mild mucilaginous ſub-

[a] Dill. 16th. [b] Herb. Sow. [c] Linn. ſpec.

ſtances are uſeful; as in diſorders of the urinary paſſages, and in coughs, hoarſeneſſes, &c. The uſe of it however has been much ſuperſeded by Marſhmallow, which poſſeſſes its valuable qualities in a ſuperior degree. The leaves alſo are not unfrequently uſed in fomentations and clyſters [1]. Woodville ſays, the roots of Malva are uſeleſs, whilſt thoſe of Althæa are of more efficacy than any other part of the plant.

It is well known that *Malva* was an eſculent vegetable among the Romans. Haller however ſays it was not this, but one allied to it, named M. rotundifolia italica, flore amplo, by Tournefort. Proſper Alpinus informs us, that a tree of the Mallow kind is eaten by the Egyptians; and the Chineſe uſe ſome ſort of Mallow in their food.]

25. This is an annual plant, with an upright ſtalk. The flowers are larger than thoſe of the common ſort, and are of a ſoft red colour.

[I have a ſtalk now before me above ſix feet in height. The petioles of the leaves are not ſo long, nor ſo hairy as in the common Mallow. The leaves and the whole plant are ſmoother. The flowers are not purple, but dark red with the veins ſo dark as to be almoſt black. The inner calyx is not ſo deeply divided, and does not fold over the fruit, which conſiſts of fewer capſules. The uprightneſs of the plant, with the colour of the flowers, immediately diſtinguiſh this from the common Mallow, which in many reſpects it much reſembles.] It was diſcovered by Tournefort in the Levant, [and cultivated by Miller, in 1759.

26. This alſo reſembles the common Mallow: but this has five ribs to the leaf, that has ſeven; this has the outer calyx lanceolate, that ovate; this has the corolla more blood-red, in that it is blueiſh purple.

It is annual, and native of the South of Europe [2]. Introduced in 1768, by John Earl of Bute. It flowers in june and july [3].

27. Stem ſtraight, ſix feet high; branches axillary: leaves cordate at the baſe, about five-lobed, the middle one ſometimes longer than the reſt: they are obtuſe, footſtalked, crenulated, ſubviſcid, ſoft, and alternate. Stipules lanceolate and entire. Flowers ſingle, axillary, with long peduncles; corolla an inch in diameter, bright purple; ſometimes more obſcure: the column of the ſtamens is marked at its baſe betwixt each of the petals with a blood-red ſpeck. The whole plant breathes a ſtrong aromatic ſmell.

Native place uncertain [4].

28. Root annual. Stems diffuſed, aſcending, rough-haired. Leaves cordate-roundiſh, ſcarcely lobed, crenate. Stipules lanceolate. Peduncles ſolitary, one-flowered, longer than the leaf. Outer calyx two-leaved, the third inner leaflet being wanting: inner calyx five-cleft, with the lobes cordate or the ſinuſes prominent. Corolla fleſh-coloured.

Native of Spain [5].

29. Root annual, three feet high. Leaves cordate, five or ſeven-angled, ſubcrenate, ſmooth, on long, alternate petioles. Flowers whitiſh red, ſmall, on one-flowered peduncles.

Native of China and Cochinchina [6]. Cultivated in 1633, by Mr. James Sutherland. It flowers in june and july [7].]

30. This alſo is annual. Stem upright four or five feet high. Leaves curled on their edges. [Stem thick, round, green, hirſute below, branched, from three to four feet high. Lower leaves a hand wide, on long petioles: the upper ones ſmaller, on ſhorter petioles, the uppermoſt very ſmall, almoſt ſeſſile, all obſcurely angular, ſinuate, bright green, pubeſcent. Flowers ſeſſile in the axils over the whole ſtem and branches, ſmall in proportion to ſo large a plant, like thoſe of M. rotundifolia in ſize and colour [8].

Native of Syria, and now become a denizon of Germany and Sileſia. Cultivated in 1596, by Gerarde. It flowers from june to auguſt [9].

31. Root long, branched, perennial. Stem from two to three feet high, round, rugged, hairy; hairs in bundles, ſpreading; branches alternate. Leaves alternate, ſemiorbicular, five-parted to the baſe, with the lobes oblong, three or five-parted, bright green, whitiſh underneath, pubeſcent, ſomewhat rugged. Petioles round, with very ſmall awl-ſhaped ſtipules at the baſe. Flowers terminating, in panicles or bundles. Calyx ſmall in proportion to the ſize of the corolla, pubeſcent; outer ſmall, inner much larger. Corolla an inch and half or two inches long, five-parted to the baſe, bright purple, with blunt two-lobed ſegments. Capſules very ſmooth, firſt green then black [10], about twenty-four in number, rounded-kidney-form, papery, marked with a raiſed line along the back, one-celled, valveleſs, opening only by the dorſal ſhield ſeparating from the ſides. The receptacle or central column is engaged or many-winged from the lateral permanent laminas of the capſules. Seeds ſolitary, kidney-form, compreſſed a little, ſmooth, aſh-coloured [11].

Native of many parts of Europe, but not of Britain, as has been generally ſuppoſed. No other than M. moſchata being found in the counties of Warwick, Leiceſter, and Nottingham, as appears from the repeated obſervations of botaniſts, who have carefully ſearched for it in thoſe counties. This differs ſo entirely from M. moſchata, that it could not well have been miſtaken or overlooked. Ray mentions but one in his own edition of the Synopſis; and what Dillenius adds in the third edition, is not from his own obſervation [12].

32. Root-leaves roundiſh, kidney-ſhaped, entire, except being crenate on the margin. Firſt ſtem-leaves three-lobed, divided half way down; ſide-lobes divided again into two or three, but not ſo deeply: above theſe they are three-lobed to the foot-ſtalk: lobes again deeply divided; diviſions deeply jagged; higher ones five-lobed, lobes pinnatifid, legments of the upper ones more and more divided, and narrower; uppermoſt linear. Stem round, much branched, ſlightly hairy: at the origin of each branch two lanceolate hairy ſtipules. Flowers crowded on the top of the ſtem and branches on ſhort peduncles, and ſingle ones from the axils of the upper leaves. Petals heart-ſhaped, divided nearly to the baſe, pale red or fleſh-coloured with deeper veins [13]. Styles fourteen to eighteen [14]. Capſules about fifteen, kidney-form, compreſſed, papery, black, thickly ſet with pale villoſe hairs, eſpecially on the back. Seeds ſmooth, pale-aſh-coloured.

This differs from the preceding, with which our Engliſh botaniſts have confounded it, in having the ſtem not ſo tall, with ſolitary upright hairs riſing from a prominent little point. Arils rough with hairs. Flowers of an ambroſial or muſky ſcent [15]. The muſky ſmell however is not always to be perceived, and the circumſcription of the upper leaves being ſometimes lengthened out into a triangular form, theſe two circumſtances have probably cauſed it to be miſtaken for M. Alcea [16].

Mr. Curtis having cultivated both ſpecies together, found M. Alcea grow nearly to twice the height of this; to be in every reſpect a ſtronger plant, and harſher to the touch; the leaves of the ſtalk much leſs jagged; the corollas ſimilar, but the calyxes remarkably different, the outer leaflets in moſchata being lanceolate or ſometimes almoſt linear; in the Alcea ovate, with a large protuberant ring near the baſe.

Native of many parts of Europe. By no means uncommon in many parts of Great Britain, particularly the midland counties, in Hertfordſhire, Huntingdonſhire, Derbyſhire, and the North frequent. In Norfolk, Suffolk and Cambridgeſhire ſparingly. Cullumhearh, South Leigh, and between Witney and Burford, Oxfordſhire. Mr. Curtis mentions its growing plentifully near Coomb-wood. I have found it near Ballam in Surry, by the five mile ſtone on the Epſom road. Gerarde ſays, it groweth by the ditch ſides on the left hand of the place of execution by London, called Tyborne; near Bulhey, on the backſide of a gentleman's

[1] Curtis, Withering. [2] Linn. ſpec. [3] Hort. kew. [4] Jacquin. [5] Linn. ſpec. [6] Loureiro. [7] Hort. kew. [8] Krocker. [9] Hort. kew. [10] Pollich and Krocker. [11] Gærtner. [12] Woodw. Mſ. [13] Ibid. [14] Withering. [15] Linn. [16] Woodw. Mſs.

house named master Robert Wylbraham; among the bushes and hedges as you go from London to a bathing place called the old Foorde; in the bushes as you go to Hackney, a village by London, and divers other places, as at Battlesbourne in Hartfordshire, three miles from Roiston. Mr. Goodyer found it with white flowers in a close near Maple-Durham in Hampshire, called Aldercrofts*. About Duplin, near Perth, &c. in Scotland*.]

33. This is an annual plant. Leaves cut into five obtuse lobes almost to the bottom, and these deeply cut on their side. The flowers stand upon very long pedunculs: the calyx is large, prickly and acute-pointed: the corolla is blue.

[Leaves blunter, ciliate, having bristles scattered over the upper surface at the ends. Stems much branched at the base, prostrate, filing. Corolla four times as large as the calyx.

Native of Provence and Spain, on the coast*.]

Gerard doubts whether this be different from M. moschata.]

34. This also is an annual plant, with stalks about a foot long, smooth and declining. Leaves on pretty long footstalks. Flowers single from the axils, and at the top in clusters. Calyxes large, acute. Corollas small, pale blue.

[Leaves sharper, ciliate, entirely smooth above. Stem upright, with alternate branches at the upper part of the stem, and none towards the root. Corollas not longer than the calyx. It is allied to the preceding*.

Native of Egypt. Cultivated in 1739, by Mr. Miller. It flowers in june and july*.

The following observations may assist in distinguishing the species. The leaves in all are alternate, undivided from one to seven, the rest angular. Stem herbaceous annual in 3, 4, 7, 8, 9, 18 to 22, 25, 26, 28, 29, 30, 33. Perennial in 23, 24, 31, 32. Shrubby in 1, 2, 5, 6, 10 to 17, 27.

The outer calyx is in general three-leaved, but sometimes in n. 12, and always in n. 28 it is two-leaved. In 13 it is sometimes four-leaved. In general it is permanent, but in 6 and 13 it is deciduous. Commonly there is a single seed only in each capsule or nut, but they are two-seeded in 18, three-seeded in 6 and 13; the capsules being divided into cells. The corolla is

Orange in 1.
Yellow, 4, 5, 7.
Pale Violet, 6.
Fiery Violet, 13.
Purple, 8, 10, 24.
Blue, 9, 19, 21, 33, 34.
Red, 14, 18, 20, 23, 25, 26, 28, 29.
Pale Rose, 16.
Flesh-coloured, 31, 32.
White, 12.
White with purple veins, 22, 30.

Gærtner remarks, that the common receptacle in all those whose fruit he has described is not cogged (molendinaceum), nor the back of the capsule soluble, as in M. Alcea; whence Medicus has separated this species from the rest under the name of *Bismalva*.]

PROPAGATION AND CULTURE.

Sow the seeds of the hardy sorts at the end of march, upon a bed of fresh light earth, and when the plants are three or four inches high, transplant them where they are to continue, allowing them sufficient space. They appear best when intermixed with other flowers of the same growth.

The seeds may also be sown in august, for most of them will endure the greatest cold of our climate, on a dry soil, and these plants will grow larger and flower sooner than those which are sown in the spring: or if the seeds be permitted to scatter, they will come up and thrive equally with those which are sown.

The seeds of those sorts which come from hot countries must be sown upon a hot-bed in the spring. When the plants are fit to remove, plant each in a small pot filled with light fresh earth, and plunge them into a new hot-bed, shading them until they have taken fresh roots: admit free air to them in proportion to the warmth of the season, and at the end of june they may be placed in the open air in a sheltered situation, where they will flower and produce ripe seeds. [Some of the species require the protection of the bark-stove.

DESCRIPTION, &c.

[This is a tall upright handsome tree, with a thick spreading elegant head. It has a long downright tap root, which renders it very difficult to transplant. Younger branchlets quadrangular. Leaves oval or obovate, quite entire, blunt, extremely shining, leathery, firm, with parallel transverse streaks, on short petioles, opposite, from five to eight inches in length. Peduncles one-flowered, short, scattered over the thicker branches. Flowers sweet, white, an inch and half in diameter. The calyx is often tribd with a five-petalled

* Gen. emac. 731. † Light. ‡ Linn. syst. § Ibid. ¶ Hort. kew.

talled or six-petalled corolla; but this arises from one of the segments or petals being cut. Fruit roundish, or obsoletely three-cornered or four-cornered according to the number of seeds, one or two of which are frequently abortive, varying in size from three to seven inches in diameter: it is covered with a double rind; the outer leathery, a line in thickness, tough, brownish yellow, divided by incisures longitudinally decussated; the inner thin, yellow, adhering strongly to the flesh; which is firm, bright yellow, has a pleasant singular taste, and a sweet aromatic smell; but the skin and seeds are very bitter and resinous. It is eaten raw alone, or cut in slices with wine and sugar, or preserved in sugar. In Martinico they distil the flowers with spirit, and make a liquor which they call *Eau Creole*. The English and Spaniards call the fruit *Mamei* or *Mammee*, and the French *Abricot-sauvage*, from the yellowness of the pulp, like that of the Abricot *.

Swartz remarks that the tree which bears hermaphrodite flowers is very lofty, but that the male trees are smaller.

Native of the Caribbee islands and the neighbouring continent. Cultivated in 1739, by Mr. Miller *.

Browne gives the hermaphrodite and male trees as different species. He informs us, that they are among the largest trees in the island of Jamaica, abound with a strong resinous gum, and are esteemed among the best timber trees; that the leaves and young branches are full of a yellow milky juice; that the fruit is large and agreeable, but too strong and gross for a weakly stomach, leaving a bitterness behind it, that continues for a considerable time upon the palate; when in a perfect state containing four rugged oblong angular nuts, having as many kernels of the same shape.]

Mr. Miller says that this tree grows to the height of sixty or seventy feet in the West Indies; that the leaves are large and stiff, and continue green all the year; that the fruit is as large as a man's fist, when ripe of a yellowish green colour, and very grateful to the taste; that it is generally sold in the markets in the Spanish West Indies, and is esteemed one of the best fruits in that country; that it has been transplanted into most of the Caribbee islands, where it thrives exceeding well.

PROPAGATION AND CULTURE.

Set the stones or seeds, as fresh as possible from the West Indies in pots filled with fresh light earth; and plunge them into a hot-bed of tanners-bark, observing to water the earth whenever it appears dry. In about a month or six weeks the plants will appear above ground, after which they must be frequently refreshed with water, and in hot weather the glasses of the hot-bed should be raised to let in fresh air. In two months the roots of the plants will have filled the pots, when you should provide some pots of a little larger size, into which you should transplant the plants, being careful to preserve as much earth to their roots as possible; then you should fill up the pots with fresh light earth, and plunge them into the bark-bed again, observing to water and shade them until they have taken root, after which they should be constantly refreshed with water as you find they want it, and must have air in hot weather. In this bed they may remain till Michaelmas, when they must be removed into the bark-stove, where they must be constantly kept, observing to refresh them with water, but sparingly at this season, as also to clean their leaves from the filth they are apt to contract in the stove; the spring following they should be shifted into fresh earth, and if they require it, into larger pots, but by no means over-pot them, for they do not produce many roots, therefore if the pots are too large the plants will not thrive, they must be constantly kept in the bark-stove, and may be treated after the manner directed for the Coffee-tree.

If, when the stones of the fruit are brought over, they are put into the tan-bed, under the bottom of any of the pots, they will sprout sooner than those which are planted in the earth.

SPECIES.

1. Manettia reclinata.

Lin. syst. 164. *Reich. n.* 345. *mant.* 558. *Swartz prodr.* 37.

Leaves ovate acute pubescent, stem reclining herbaceous.

2. Manettia Lygistum.

Swartz. prodr. 37.

Petesia Lygistum. *Lin. syst.* 153. *Reich. n.* 313. *Swartz obs.* 47.

Lygistum. *Browne. jam.* 142. *t.* 3. *f.* 2.

Leaves ovate acute veined, stem twining suffrutescent.

3. Manettia lanceolata.

Vahl symb. 1. 12.

Leaves lanceolate, flowers five-stamened.

DESCRIPTIONS, &c.

1. Root annual. Stem weak, branched. Leaves opposite, approximating, subciliate, an inch and half long. Petioles very short, hirsute. Stipules opposite, fastened to the petioles, pressed close, semicircular, very short. Pedunckes axillary, solitary, shorter than the leaves, many-flowered: pedicels opposite, round, hirsute. A bracte to each pedicel, minute, acute. Flowers white.

Native of Mexico *.

2. This weakly shrub rises by a very branched flexuose stem to the height of about seven feet, and is every where adorned with moderately large ovate leaves disposed in an opposite order. The twigs or boughs begin to shoot almost immediately above the root; and they, as well as the succeeding branches, rise generally to the height of the main stem, and are furnished with moderate bunches of flowers towards the top, which generally rise by long branched pedunckes from the axils *. The calyx is eight-leaved, and the seeds imbricate, as in the preceding *.

Native of Jamaica.

3. Stem shrubby. Pedunckes terminating; often in threes, the side ones three times as long as that in the middle, bifid at top. There is a lanceolate leaflet at the division of the pedunckes. Flowers at first heaped,

* Linn. mant. * Browne. * Swartz obs.

then in racemes, directed one way; with bristle-shaped leaflets at the base of the calyx. Capsule crowned with the calyx. It agrees with Manettia in the corolla, nectary, stigma and pericarp; differing only in the number of stamens and segments of the calyx.—Allied to Cinchona[1].

Racemes elongated, petals ovate and reflex, drupe cordate pubescent.]

DESCRIPTIONS, &c.

1. This is a large spreading tree. The wood is brittle, brown and used only for indifferent work[1]. The bark becomes rugged by age. The leaves are seven or eight inches long, and two or more broad, [lanceolate, quite entire, smooth, of a fine shining green and a paler resinous smell[2]] terminating in points, and having several transverse parallel opposite ribs; [they are on short petioles[3], and grow in bunches at the extremity of the branches[4].] The flowers are produced in loose bunches at the end of the branches. [The calyx consists of five, acute, spreading leaflets; the corolla, which is inferior, of five oblong flat petals, reflex at the tip, white with yellow streaks at the base, longer than the calyx: nectary spheroidal, large, fleshy, five-lobed, compressing the germ. Stamens shorter than the corolla, with five ovate nodding anthers. Style short. Drupe large, covered with a smooth, loftish, resinous, pale green, yellow, or half red skin, and containing an ovate woody fibrous compressed nut or stone, within which is an ovate fleshy kernel[5].—Gærtner thus describes it more particularly. It is a berried drupe, flatted like a bean, kidney-shaped; the flesh soft and pulpy, like a damascene Plum; the shell ovate-oblong, almost kidney-shaped, of a leathery crustaceous substance, hard, one-celled, valveless, on the outside grooved and wrinkled, covered all over with capillary woody fibres, smooth within and lined with a whitish papery membrane, very tough and smooth, separating from the shell or stone when ripe. Umbilical chord very short, arising from the bottom of the shell, and inserted into the margin of the seed at the lower part. Skin little, papery, thin. Albumen none. Embryo upright, white: cotyledons fleshy, plano-convex: radicle short, curved in upwards, inferior.

This fruit, when fully ripe, is yellow and reddish, replete with a fine agreeable juice; some are full of fibres, and the juice runs out of these on cutting, or with a little handling; but those which have few or no fibres are much the finest; they eat like an apple, but are more juicy, and some are as big as a large man's fist. It is esteemed a very wholesome fruit, and except very fine Pine-apples is preferable to any fruit in India; gentlemen there eat little other fruit in the hot months; but if no wine be drank with it, the Mango is apt to throw out troublesome boils, at least with new comers, which are however conducive to health[6].] In Europe we have only the unripe fruit brought over in pickle.

It grows naturally in most parts of India, also in the Brazils, and some other parts of the world; [as Cochinchina, Pegu, &c.

It was cultivated in 1690, in the Royal garden at Hampton Court[7].]

Mr. Miller, in his last folio edition of the Dictionary (1768) says, that a Mango plant was brought over by Captain Quick, and was then in good health in the Chelsea garden; the plants that were in England before having been destroyed by too much heat.

[Linnæus, not having an opportunity of examining the fructification with accuracy, could not determine this genus with certainty; he had several in his herbarium, but he regarded them as varieties only of the cultivated Mango. Loureiro remarks, that there are many varieties, differing chiefly in the figure, size, colour, and taste of the fruit, as Apples and Pears do in Europe. Retzius on the contrary affirms, that there are certainly several distinct species; the number of stamens in some being double; the racemes in others compound; the fruit kidney-shaped, globular, fleshy, almost juiceless, &c. Gærtner has distinguished some of the most remarkable varieties by the fruit.

β. Shell large, about a span in length, in a manner leafy at top, but having a small lenticular cell below; grooved and crimite in the other parts like the cultivated sort.

γ. Shell very turgid, in other respects very like the preceding, except in being a third part shorter.

δ. Shell extremely like that of γ, but scarcely grooved, being only striated here and there.

ε. Shell less by half than the preceding varieties, but a little turgid and deeply grooved.

ζ. Shell the size and shape of that of an Almond, leathery, thin, brittle, white, neither grooved nor striated, but rough with very gross fibres.

He adds, that in all these varieties the embryo is regularly divided into two cotyledons; whereas in the cultivated sort the lobes are most usually united and split into various irregular partial lobules.

Doubtless many more varieties might be added by people of the countries where this tree grows naturally.

M. Amba of Forskahl, which Gmelin has given as a distinct species, is probably not different from M. indica, in which Jacquin (ic. vol. 2. and collect. 4. 97.) has found the filaments such as Forskahl describes them in Amba[1].

Rottboel in nov. act. dan. 2. 534. t. 4. has a species which he names Mangifera glauca, and which Gmelin has also adopted under the same name. It is Celastrus glaucus of Vahl, 2. 42. Schreberi of Retzius, 6. 25. And properly a species of Elæodendrum.

Linnæus doubts whether all the flowers in M. indica

[1] Vahl. [2] Loureiro. [3] Ibid. [4] Ives. [5] Loureiro. [6] Ives, voy. 184. [7] Hort. kew. [1] Linn. trans. 2. 226. See Linn. zeyl. n. 472.

be hermaphrodite. Loureiro affirms that he has always found them so.

2. Leaves a foot long, unequally pinnate: the leaflets oblong and quite entire. The flowers in a large panicled raceme. Linnæus refers it to this genus on the authority of Koenig, who had examined the living plant, and had seen the fruit[a]. It appears however to be of a different genus; the flowers having ten (seldom eight) stamens and five styles; the nut being five-celled and five-seeded, with a cover like that of the Nutmeg, but callous[b].

Native of the East Indies.

3. This is a large tree, with the bark somewhat rugged, and ascending branches. Leaves lanceolate, quite entire, but three times the size of those of the common Mango, dark green, scattered, on long petioles. Flowers red, terminating, in oblong racemes. Corollas reflex from the base, acute, five-petalled. Drupe fleshy hirsute, roundish, cordate, strong smelling, of an acid flavour and unwholesome. Nut roundish, fibrous.

The wood, though not very good, is useful for floors, and lasts very well, if it be soaked a considerable time in muddy water[c].

Native of the East Indies and Cochinchina.]

PROPAGATION AND CULTURE.

The vegetative quality of the nuts not seeming to be long preserved, the readiest method to obtain plants of Mango in Europe, is to set a quantity of the nuts in a tub of earth in the country where they grow naturally, and when the plants are grown a foot high, to ship them, placing a covering over them to defend them from the water and spray of the sea, being very careful not to water them too much in the passage: when the ship arrives in a cold climate, screen them from cold. This tree will not thrive in the tan-pit. Set the plants therefore in pots filled with light kitchen-garden earth, and place them in a dry stove, where in warm weather they should have fresh air daily, and in winter the air should be kept up to temperate, as marked on the thermometer.

[The nuts should be sent over in wax to preserve their vegetative quality. The Mango may be increased here from cuttings, in the same manner as Gardenia.

Class. 23. 1. Polygamia Monoecia.

Nat. order of *Gramina*, *Graminæ* or *Grasses*.

GENERIC CHARACTER.

* *Hermaphrodite flowers, in the adverse side of the flexuose jointed spike, imbricate, alternate, each immersed in each joint, which is excavated on one side.*

CAL. *Glume* one-flowered, two-valved: *outer valve* larger, coriaceous, roundish, rugged in the middle, emarginate or entire at the top and sides; *inner* smaller, broad-lanceolate, membranaceous, pressed close to the outer.

COR. *Glume* two-valved, membranaceous, thin, diaphanous, smaller than the calyx, included: the outer with its margins embracing the inner, which is smaller. *Nectary.*

STAM. *Filaments* three, filiform, standing out. *Anthers* oblong, incumbent.

PIST. *Germ* ovate. *Styles* two, short, filiform. *Stigmas* oblong, bearded, spreading, standing out on both sides.

PER. none. *Calyx* cherishing the seed.

SEED single, ovate.

* *Male flowers marginal, alternate, in the back of the spike on each side.*

CAL. *Glume* one-flowered, roundish, two-valved: *valves* parallel, ovate-lanceolate, blunt, striated, leathery, augmented by a membrane, almost equal.

COR. *Glume* two-valved, membranaceous, thin, almost the size of the calyx: *outer valve* ovate, blunt, convolute; *inner* lanceolate, plaited, scarcely longer. *Nectary.*

STAM. *Filaments* three very short or none. *Anthers* as in the hermaphrodites.

OBS. *The inner calycine glume of the hermaphrodite flowers, in* M. myurus *at least, is certainly not glued to the ovarium, as it is described and figured by the younger Linnæus.* S.

ESSENTIAL CHARACTER.

HERM. *Cal.* Glume two-valved, one-flowered, outer valve emarginate at the top and sides. *Cor.* less than the calyx. *Stam.* three. *Style* bifid.

MALE as in the hermaphrodites, but with the flowers in the lower side of the same spike standing out more.

SPECIES.

1. Maniseris myurus.

Lin. syst. 907. *mant.* 300. *Reich.* 4. 318. *Swartz prodr.* 25.

Spikes lateral, outer valves flat ovate, emarginate at the top and sides, calm ascending.

2. Maniseris granularis.

Swartz prodr. 25. *Gærtn. fruct.* 2. 468.

Cenchrus granularis. *Lin. syst.* 907. *mant.* 575. *Reich.* 4. 315.

Gramen cyperoides, &c. *Sloan. jam.* 1. 128. *t.* 80.

Spikes lateral, outer valves orbicular, callous-dotted, sheaths hairy, culm erect.

DESCRIPTION, &c.

1. Culms ascending or diffused, jointed, even, the thickness of a large thread, a foot high, branched towards the base, and with alternate spike-bearing branches at top. Leaves even, sheathing, spreading, narrower; with thickish sheaths, shorter than the internode. Floral leaves at the base of the peduncle, without sheaths, erect, convoluted like the glumes, lanceolate. Spikes (three or four on a culm) solitary, lateral and terminating, peduncled, twice as thick as the culm, fingered, imbricate, more closely so at the back, somewhat jointed, punched with a few holes as it were with emarginate scales; on the lower side (next the ground) jointed and bifariously squarrose: florets striated, roundish, a little prominent.—Native of the East Indies[a].

2. This has been already described from Linnæus's mantissa, under Cenchrus granularis, which see. It has however the character of Maniseris, and therefore is justly placed in this genus by Swartz and Gærtner. The latter observes, that the calyx of the hermaphrodite flowers when ripe becomes hard, almost like the shell of a nut, including the seed very tight, and not letting it drop: and that the seed is small, roundish, convex on one side, flattish on the other, and red. Sloane's synonym is quoted by Linnæus under Panicum clandestinum.—It is a native of Jamaica[b].

MANNA ASH. See *Fraxinus*.

MANORI. See *Glycine*.

MANULEA.

Lin. gen. Reich. n. 830. *Schreb. n.* 1032. *Gærtn. t.* 55. *Juss.* 100.

Class. 14. 2. Didynamia Angiospermia.

Nat. order of *Perforatæ*. *Pedicularis*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* five-parted: *segments* linear, erect, equal, permanent.

COR. one-petalled, irregular. *Tube* cylindric, with the throat rather wider. *Border* five-parted, awl-shaped, spreading:

[a] Suppl. [b] Retzius. [c] Loureiro.

[a] Linn. mant. [b] Swartz.

spreading: the four upper divisions more connected at the base; the lowest reflex.

STAM. *Filaments* four, very short. *Anthers* the two upper in the throat, the two lower somewhat oblong, within the tube.

PIST. Germ superior, roundish. *Style* filiform, the length of the lower stamina. *Stigma* simple.

PER. *Capsule* ovate, the length of the calyx, two-celled, two-valved: the valves when ripe semibifid. *Partition* doubled, by the inflex margins of the valves.

SEED. very many, small. *Receptacle* oblong, compressed, in the axis of the capsule.

ESSENTIAL CHARACTER.

Cal. five-parted. *Cor.* with a five-parted awl-shaped border, the four upper segments more connected. *Caps.* two-celled, many-seeded.

Selago hirta. *Lin. fyst.* 569. *suppl.* 285[b].
Rough-haired, leaves obovate, spikes very long.

DESCRIPTIONS, *&c.*

1. This is an annual. The herb has the stature of Euphrasia. Stem a hand high, branching from the base to the middle in several upright round naked stemlets. Leaves alternate, obovate-oblong, sessile, serrate, on the upper branches small. Racemes terminating, upright, longer than the plant. Bractes linear, shorter than the calyx. Peduncles also shorter than the calyx. Corollas deep yellow[a].

2. Root biennial. Stem a foot or a foot and half high, and woolly. Branches opposite, not alternate, as Linnæus describes them; in this perhaps they may vary. Leaves opposite, sessile, obovate, narrowing to the base, toothed on the edge, which is rolled back a little in the young leaves. Flowers in a long thyrse, from two to five from one common short peduncle: they are at first lemon-coloured or greenish yellow, finally deep orange.

Linnæus says that the whole of the plant except the corolla is woolly, the tube even of that is hairy; the segments are smooth with their edges rolled back; the upper part of the tube, in which the filaments are inclined, is somewhat dilated, as is also the lower part, so that it is narrowest in the middle. The flowers appear from may to november, and are usually followed by seeds, from which the plant may be propagated. The flowers have a fingular, but unpleasant smell, not perceivable at a distance. The variety of pleasant colours so conspicuous in the flowers renders this a very desirable plant[b].

Linnæus remarks that Selago lychnidea seems to be allied to this species.

Introduced in 1774, by Mr. Francis Maſſon. It flowers from may to november[c].

These and the subsequent sorts are natives of the Cape of Good Hope. They were mostly found by Thunberg, and are only registered in the Supplementum Plantarum of the younger Linnæus, and in Systema Vegetabilium.

18. The capsule of Manulea hirta is described by Gærtner as small, ovate-oblong, with a groove on each side: receptacle central, columnar, oblong, compressed a little, not fattened to the partition. Seeds subglobular, obsoletely angular, with small excavations in rows, white. He remarks that not only this, but all the many-seeded Selagos should be removed from that genus.

MANURES.

Every substance that when laid on land or mixed with the soil promotes vegetation, or increases its fertility, is called a manure.

Manures operate in all the different ways by which vegetation is promoted. By communicating to the soil with which they are mixed the vegetable food which they contain. By communicating to it a power of attracting this food in greater plenty from the air. By enlarging the vegetable pasture. By dissolving the vegetable food which it is already possessed of, and fitting it for entering the roots of plants.

Some manures afford nourishment only: as rape-dust, soot, malt-dust, pigeon's-dung, and in general all top or hand-dressings.

Others give nourishment, and also add to the soil, as animal dungs, and all rotten animal and vegetable substances.

Others again open the soil, and do not nourish in their own nature: as lime, light marls, sand, &c.

Lastly, other manures lighten the soil, and at the same time nourish a little: as clay, clay marls and earth.

Manures are considered by different authors as simple and compound; as natural and artificial; nutritious and stimulating; or solvents and mucilages; mechanical or chemical; as animal, vegetable, and mineral. All these distinctions may have their use, and are each attended with difficulties and liable to objections. Some

[a] Linn. mant. [b] Curt. magaz. [c] Hort. kew.

method

method however being neceſſary in treating a ſubject which embraces a great variety of objects, manures are here in general thrown into the three great diviſions of animal, vegetable and foſſil. After theſe have been treated ſeparately, Compoſts, and their improvements not ſo properly called Manures will conclude this treatiſe; in which it is not propoſed to enter much into the theory of Manures, or to give a philoſophical diſquiſition on the ſubject, but rather to lay before the reader the reſult of a variety of experience and practice. The theory may be learnt from Dr. George Fordyce's Elements of Agriculture and Vegetation. Home's Principles of Agriculture and Vegetation. Hunter's Georgical Eſſays. Cullen's Lectures on Vegetation and Agriculture. Ingenhouſz's Treatiſe on the Food of Plants, and the renovation of Soils. Headlicke's Eſſay on Manures. Kirwan on Manures. Haſſenfratz Annales Chymiques, Duhamel, Tillet, Bergman, Prieſtly, Lavoiſier, Senebier, &c. &c.

Manures are confeſſedly very different in their nature. Some of them operate in all the ways abovementioned; and there are none that do not operate in more ways than one.

It is a fundamental miſtake to ſuppoſe with Tull that Tillage may be ſubſtituted in the place of manure. Manures will indeed be of little avail without it; but although good tillage, by ſeparating the ſoil may bring a greater number of nutritious particles within the reach of the crop, yet the ſoil cannot poſſibly continue to be ſo completely divided as it is by the fermentation excited by dung and other manures; which are found to enrich the beſt pulverized ſoil again and again, after it is exhauſted by crops; and therefore promote vegetation by increaſing the quantity of vegetable food.

Some manures loſe part of their ſtrength by being long expoſed to the air. Thus after dung is ſufficiently fermented, the longer it lies, the leſs is its value. Cow-dung dried on the paſture, gathered and laid upon other land, has ſcarcely any effect; whereas the ſame quantity carried from the cow-houſe, or collected by folding the cattle, enriches the land. Hence this kind of manure contains the vegetable food in itſelf, and does not receive it from the air.

Other manures on the contrary operate ſooner and with greater violence, the longer they are expoſed to the air, before they are uſed. Lime and marls are of this kind. They are obſerved to have a ſtrong power of attracting certain qualities from the atmoſphere; and operate by communicating to the ſoil with which they are mixed a power of attracting vegetable food from the air.

Again, ſome manures exhauſt land of its vegetable food, and do not reſtore it again when immediately applied. This is thought to be the caſe with Lime. Land thoroughly limed, after having carried many very good crops, ſeems to be exhauſted, and reduced to a worſe ſituation than before. When in this caſe lime has been applied a ſecond time, its effects have been found to be far inferior to what they were when firſt applied. This manure therefore ſeems to operate by diſſolving the vegetable food which it meets with in the ſoil, and fitting it for entering the roots of plants.

It ought however here to be remarked, that exhauſtion of land by lime is owing to bad management and unmerciful forcing of it with continued white crops. It is not certain that land will not bear a ſecond liming. It is certain that the effect of the lime may be long kept up by the proper application of dung and other oily manures; and there have been inſtances of the effect of lime continuing forty, fifty, or even a hundred years.

Certainly all kinds of manures contribute to open the ſoil. Any perſon may be convinced of this, who will take the trouble to compare a piece of land on which dung or any other manure has been laid, with a piece contiguous that has not been manured: he will find the former much looſer, much more free and open than the latter. It muſt be allowed therefore that all manures operate by enlarging the vegetable paſture*.

* Hunter's Georg. Eſſays. 19

Manures are applied to ſupply either the nutritive ingredients of a ſoil, to improve its texture, or to correct its vices.

For *clayey* ſoils the beſt manure is Marl, and that which is moſt calcareous is beſt.

Theſe ſoils are defective both in conſiſtence and texture; they want the calcareous ingredient and coarſe land. Calcareous marl ſupplies the firſt chiefly; limeſtone gravel will ſupply both.

A mixture of marl and dung is ſtill more advantageous, becauſe the dung ſupplies the carbonaceous ingredient. But the ſame quantity of marl muſt be uſed, as if no dung had been applied; or elſe the operation muſt be more frequently repeated.

If marl cannot be had, a mixture of coarſe ſand and lime perfectly effete or exſtinguiſhed, or chalk, will anſwer the ſame purpoſe, as it will ſupply the defective ingredient, and open the texture of the clay. So alſo ſand alone, or chalk, or powdered limeſtone may anſwer, though leſs advantageouſly. Lime alone ſeems leſs proper, as it is apt to cake, and does not ſufficiently open the ſoil.

Where theſe manures cannot be had, coal-aſhes, chips of wood, burned clay, brick-duſt, gravel or even pebbles are uſeful; for all theſe improve the texture, and the former ſupply alſo the carbonaceous ingredient.

Nothing perhaps is equal to good ſtable and ſold-yard dung for ſtrong tillage lands, becauſe it opens this heavy ſoil at the ſame time that it ſupplies the richeſt nutriment. But dung is a proper ingredient in the appropriated manures of all ſorts of ſoils, as it ſupplies the carbonaceous principle.

Clayey Loam is defective either in the calcareous ingredient, or in the ſandy, or in both: if in the firſt, the proper manure is chalk; if in the ſecond, ſand; if in both, ſhelly marl, or lime-ſtone gravel, or effete lime and ſand.

Chalky ſoil wants both the clayey, and the ſtony ſandy or gravelly ingredients, the beſt manure for it therefore is clayey loam or ſandy loam; but when the chalk is ſo hard as to keep of itſelf the ſoil ſufficiently open, then Clay is the beſt manure, for in ſuch caſes the coarſe land of gravelly ingredients of loams are of no uſe. Some indeed think, that pebbles in a field ſerve to preſerve or communicate heat; this uſe however is not ſufficiently aſcertained. They detain moiſture, and thus on chalk lands a complete covering of great black flints inſures a tolerable crop in a dry ſeaſon.

Chalky Loam. The beſt manure for this ſoil is clay or clay-marl; becauſe it is defective principally in the clayey ingredient. Light limeſtone ſoils, not differing eſſentially from theſe, require the ſame manure.

Sands. The beſt manure for theſe is calcareous marl, for they want both clay and calx, and this marl ſupplies both: the next beſt is clay-marl, and next to theſe clay mixed with lime, or calcareous or clayey loams. Lime or chalk are leſs proper, becauſe they do not give ſufficient coherence to the ſoil; however, when mixed with earth or dung, theſe anſwer well, becauſe they form a ſort of marl or compound comprehending the defective ingredients.

Sandy Loams are defective chiefly in the calcareous ingredient, and in ſome degree alſo in the argillaceous: their texture alſo is imperfect, as they abound both in fine and coarſe ſand: chalk or lime would ſupply the firſt defect, but leave the texture unamended. Calcareous or argillaceous marls are moſt proper. Clay, after land has been chalked, anſwers well, becauſe it remedies the texture.

Gravelly Loams are benefited by the application of marl, whether argillaceous or calcareous. If the gravel be calcareous, clay may be employed. A mixture of effete lime and clay ſhould anſwer in all caſes.

Farruginous Loam or *Till* and *Peaty* ſoils neceſſarily require the calcareous ingredient to neutralize their peccant acid: hence chalk, limeſtone gravel and calcareous marl are moſt advantageouſly applied to them.

Bogs or boggy ſoils, muſt be firſt drained, and then the nature of the ſoil being explored, an appropriate

manure muſt be applied. In general they ſhould be burned, and then covered with limeſtone gravel or lime mixed with coarſe ſand or gravel, becauſe they are uſually of a clayey nature; if they are more ſandy, lime may anſwer well, or calcareous marl. If their upper parts contain a ſufficiency of the carbonaceous principle, as often happens, they need not be burned.

For all moiſtiſh and cold ſoils, gravel, road-dirt, ſmall ſtones, coal-aſhes, ſoaper's aſhes, hog-dung, &c. are good. But in cold wet lands, no manure can be effectual without draining.

Heathy ſoils ſhould firſt be burned to deſtroy the heath, and increaſe the carbonaceous principle. Lime alſo will deſtroy heath. Limeſtone gravel is the fitteſt manure when the ſoil is clayey, lime when it is gravelly. Gypſum alſo anſwers remarkably well when the ſoil is dry[5].

Manure is uſually applied in three different ways. The firſt and moſt common is that of ploughing it in, and thus mixing it with the whole ſoil. This is the beſt ſyſtem where it is neceſſary to enrich a field for a ſucceſſion of exhauſting crops; and alſo in ſtrong heavy lands, which require to have their parts ſeparated as much as poſſible; which effect is produced by nothing better than by ploughing in long dung or green crops. It may perhaps be queſtioned whether this be the beſt means to make the moſt of the manure, as ſome valuable parts of it may be ploughed in too deep, and even entirely loſt. The ſecond is, ſpreading or ſcattering the manure upon young crops, which is called Top-dreſſing or hand-dreſſing. This mode is confined to particular ſubſtances, as ſoot, rape-cake, pigeon's-dung, aſhes, &c.; and has been found to anſwer, eſpecially with crops which tiller, as wheat and barley. Even dung, well rotted and made into a compoſt with earth, lime or other active ſubſtances, may be thus employed, and being applied on the ſurface, and at a ſeaſon when the crop ſtands moſt in need of it, a much leſs quantity of manure will be ſufficient; but then it will be of little or no uſe to ſucceeding crops, and the expenſe of preparing it will be greater. When crops are ſickly or backward in the ſpring, top-dreſſings are certainly of great uſe, except the ſeaſon ſhould prove uncommonly dry.

The third way of applying manure, is laying it into drills, and ſowing the crop upon it. This is uſed only for particular crops, as potatoes, turneps, &c. which thus receive the whole benefit of the manure, in all ſtages of their growth.

DUNG

Is the moſt common, general, and upon the whole the moſt efficacious of all manures. It is properly the excrement of animals, but is uſed alſo to ſignify all rotten vegetables, when uſed as manures.

Dung promotes vegetation by increaſing the vegetable food, by enlarging the paſture of plants, by communicating to the ſoil a power of attracting the vegetable food from the air, and by preparing the vegetable food for the nouriſhment of plants[6].

Dung of Quadrupeds, is the moſt common manure in uſe.

Stable dung is uſed either freſh or putrified; the firſt is called *long*, the ſecond *ſhort* dung. It abounds in animal matter, eaſily putrifies, and ſerves to haſten the decay of other dead vegetable ſubſtances. Its fermentation is promoted by frequent turning and expoſure to the air: yet it ſhould be covered to prevent water from carrying off moſt of its important ingredients; or at leaſt the water that imbibes them ſhould not be loſt.

Farm-yard dung conſiſts of various vegetables, chiefly ſtraw, ſometimes weeds, leaves, fern, &c. impregnated with animal matter: it ferments more ſlowly than ſtable dung, ſhould be piled in heaps, and ſtirred from time to time: fern in particular putrifies very ſlowly[7].

Management.

When any conſiderable quantity of ſtable or yard dung, or other mixture of animal and vegetable ſubſtances is collected together in a heap, and ferments; when this proceſs is completed, if the maſs be examined, we find that the vegetables of which it was originally compounded are decompoſed, and in a ſituation to nouriſh new plants. The more completely therefore theſe ſubſtances are ſubmitted to the proceſs of fermentation, the more beneficial will be their effects upon the ſoil. Hence it is an object of the firſt importance to Farmers to have their dunghills ſo ſituated and conſtructed as to promote their fermentation, and retain all the uſeful parts of them.

Theſe circumſtances have been very little attended to: the greater part of dunghills, being either placed in hollows, and ſurrounded with water, which effectually prevents fermentation by chilling them; or upon declivities where every drop of moiſture runs away: cattle are allowed to ſpread it by trampling, weeds to exhauſt it, and carts and waggons are driven over it. Thus the middle, from being hard preſſed, will be imperfectly fermented, and the ſides, from being ſcattered about and dried, will not be fermented at all, but in a condition little better than dry ſtraw.

To promote fermentation in dung, air and moiſture are neceſſary. It is well known to gardeners that in making hot-beds, by laying the dung lightly in heaps, and watering it gently, fermentation is immediately brought on: and that hot-bed dung is as completely fermented in a fortnight, as that in a farm-yard generally is in ſix or eight months.

The farmer ſhould imitate this practice as nearly as the nature of his ſituation will admit, and inſtead of having his dunghill in the yard, and allowing carts, cattle, &c. to diſturb it, he ſhould place it in ſome diſtinct ſituation, convenient for his offices, where the urine may be kept with it, or elſe run into a receptacle, whence it may be thrown back into the dung to enrich it and promote the fermentation, or be carried off in carts to manure his land.

When dung is carried to the dunghill, it ſhould not be driven over the heap as is commonly practiſed, becauſe the feet of the horſes and the weight of the carriage will preſs it ſo hard as to exclude the air, and thereby prevent the fermentation: when the quantity alſo is conſiderable, the horſes are ſtrained, and the harneſs damaged by the exertions neceſſary to drag a loaded carriage over a hill of ſuch looſe materials. Every load therefore ought to be laid down by the ſide of the dunghill, at leaſt after the work has made ſuch progreſs as to render paſſing over it a matter of difficulty, and afterwards thrown up lightly with a fork, the labour of which is trifling in compariſon with the advantage reſulting from it.

If dung laid up in this manner contains a ſufficient proportion of moiſture, it will immediately begin to ferment; if therefore it is too dry, it ſhould be watered, and in ſummer this will frequently be found neceſſary: it will thus be completely fermented in ſix or ſeven weeks, and will be more valuable by half than that which is made in the common ſlovenly manner. The ſituation beſt calculated for a dunghill is that which is neareſt to a level, with a bottom capable of retaining moiſture, and covered with a ſhed.

If the whole be incloſed with a wall, except an open ſpace at one end for carting away the dung, it will be a great improvement. The wall on the ſouth ſide ſhould be of ſuch a height as entirely to prevent the ſun's rays from reaching the dung, on the other three ſides ſix feet in height from the ground will be ſufficient. The roof may be thatched, and ſupported on pillars. If the bottom be not clay or chalk naturally, it muſt be laid with one of thoſe ſubſtances, and the upper part ſhould be paved with broad flags or common paving ſtones. At the end oppoſite to the opening a reſervoir may be dug to receive the moiſture: it ſhould be water-tight, and a pump ſhould be put into it to draw off the moiſture daily. This may be thrown back on the dung-heap, or drawn into a barrel on a cart, and either ſpread immediately on the land, or mixed with other ſubſtances in a compoſt.

Application.

Dung is applied indiſcriminately upon all ſoils, at almoſt any ſeaſon, and for every crop. Of all manures commonly in uſe none can be conſidered as a more immediate food for plants, and when applied to vege-

[5] Kirwan in V. Ann. 23. [6] Hunter's Eſſ. 18. [7] Kirwan in V. ann. 23. 91.

tables in a growing ſtate, they immediately begin to thrive. On this theory it ſeems abſurd that great quantities of rich dung ſhould be laid upon the fallows at the end of autumn, and ſtill worſe about Midſummer, there to remain till the enſuing ſpring before it can be of any uſe to the plants: for if the fallow be ſown with wheat or any other winter crop, the growth of the plants being ſtationary, they need little nouriſhment; in the mean time the ſalts contained in the dung, after having been ſpread abroad a month, or perhaps ſix weeks, diſſolving readily in water are carried off by the winter rains; and when the ſpring arriving the plants begin to vegetate, a great part of what was deſtined for their nouriſhment has been waſhed away and loſt.

Farther, where fallows have been well wrought, and the ſoil thus completely reduced, mixing it with dung in that ſtate prevents it from acquiring a ſufficient degree of compactneſs to ſhelter the roots of the plants, eſpecially if the ſoil be naturally of a light open texture, and the dung full of half rotted ſtraw, as is commonly the caſe. The operation of the winter's froſt renders it ſtill looſer, ſo that in ſpring it is nearly in the ſtate of a mole-hill; the baneful effects of which to a wheat crop are obvious. Now were a portion at leaſt of the dung withheld till the ſpring, the land would be more compact, the plants leſs liable to be thrown out of the ground by the froſt, and the dung being applied as a top-dreſſing at the time when vegetation was commencing, the uſeful parts of the dung would be taken up by the plants, every time it was moiſtened, as the crop in its progreſſive growth moſt wanted it. In this mode of application no part of the dung would be loſt, and a leſs quantity being required for the dreſſing, three times the quantity of land might be dreſſed annually; and being applied in a quantity ſufficient only for the nouriſhment of the crop, the plants are fed in the ſame manner as the animal body, every ſmall doſe operating like a meal.

Some are of opinion that the firſt rank quality of dung is highly beneficial, and its principal virtue. Mr. Belcher on the contrary is inclined to think that it is more or leſs injurious, greatly ſo in horſe-dung, which is evidently unfit for plants when new. In his opinion the beſt mode of uſing all dung, except in compoſt, on cold ſtiff ground eſpecially, is to carry it on rough, and to fallow that and the ſoil together, whereby at the ſame time that they are incorporated, the ſeeds of weeds are forced into vegetation, and completely deſtroyed *.

The common practice is to ſet the dung upon the land in ſmall heaps or hillocks, and to ſpread it by a man ſtanding on the ground. In ſome of the Midland Counties the prevailing cuſtom is to ſpread it out of the carriage, as it is brought into the field, by a man or men ſtanding in the carriage †.

Dung ſhould never be moved in ſummer. The immediate action of the ſun's rays exhauſts it of its moiſture, and it is an erroneous idea that this evaporation carries off merely aqueous particles; the ſalts, the oils rendered miſcible with water by alkaline ſalts, or calcareous earth, and the inflammable air are all diſſipated with the water. To turn a dunghill over, then to throw it into carts, expoſe it in heaps, and to ſpread it a ſecond time in ſummer, is to give the ſun a power of nearly exhauſting its virtues ‡.

A Hertfordſhire farmer on the contrary never carries dung out to cheoſe in winter, thinking that the rains, &c. damage it much, but in ſummer he does not think its being expoſed to the ſun a detriment, ſuppoſing the heat to exhale only the watery particles. He has found one load laid on at Midſummer as good as two or three at Chriſtmas. The freſher the dung is uſed, the better he thinks it for any crop, even for graſs, provided it be laid on early in autumn. He has found long dung of only one or two months old to be better, load for load, than black ſpit dung for turneps. In forming a dunghill, he ſays the dung will not rot if the carts drive on to it, but if the dung be ſhot on of the carts by the ſide of the hill, and then thrown up, without any trampling, it will rot much ſooner and better. This alſo is the Norfolk practice §.

At whatever time the dung is carried on the land, it ſhould be ſpread and ploughed in as ſoon as poſſible.

It is ſaid to be a wrong practice to lay dung upon Clover-leys in autumn: for if the field be to remain another year in graſs, not only a part of the dung is waſhed away by the winter rains, but the remainder injures the plants; it being well aſcertained that the action of dung upon broad Clover, when the plants are not in a growing ſtate, is fatal to them. But in the ſpring a light top-dreſſing of dung is highly uſeful to broad Clover, though foot is preferable.

If the Clover-ley is to be ploughed for Wheat, and dung be laid on; if the graſs crop has been good, the furrow will be turned over entire, and the dung laid flat under it, and as the roots of the Wheat muſt penetrate through the ſod before it can reach the dung, little benefit can be expected from it, allowing the qualities of the dung to remain unimpaired: but in this caſe the loſs from the winter rains will be greater than when dung is laid on fallow; for there being incorporated with the ſoil, a part of the ſalts will be entangled with the earth; but upon ley, it is either laid in the bottom of the furrow, or if the ſod be ſet on edge, it remains crammed into the interſpaces through which the whole of the rain paſſes. Whenever Wheat therefore is ſown upon ley, the dung ought to be uſed as a top-dreſſing in the ſpring, when every part of the crop will have the benefit of it, and the harrows having looſened the top of the furrow ſo that the moiſture of the dung will readily enter it, no part of the dung will be loſt.

If the ley is to be ploughed for Oats, provided the land was well laid down, there is no occaſion for dung; but if the land be poor, and dung is required, it cannot be employed in any way ſo uſeful, as in the form of a top-dreſſing at the time when the ſeed is ſown.

Perhaps there is no way in which dung is uſed where its effects are ſo certain and viſible as upon Potatoes and Turneps. For Potatoes it is laid on when the ſpring is pretty far advanced, after which there are few heavy rains, of courſe the ſtrength of the dung is not impaired by waſhing, and the crop is left in quiet poſſeſſion of the whole of its fertilizing powers. For Turneps the caſe is nearly the ſame; indeed the advantage is ſtill greater, dung not being laid upon Turnep land ſooner than June, after which there is ſeldom much wet weather till autumn, and by that time the crop is in full vigour.

As to laying dung upon Meadows farmers differ in opinion: ſome preferring the ſpring, for producing an early vegetation and a plentiful crop; others thinking, that though dreſſings of ſoot and fine aſhes at that ſeaſon are of much uſe, yet that dung ought to be laid on at the end of autumn, not to take the juices of the enſuing crop.

It is thought to be a good practice by ſome to ſpread the dung as ſoon as the hay is cleared. If laid on in the winter, or early in the ſpring, the froſt will take effect upon the manure before the graſs can reap any advantage; and the rains coming waſhe the manure is expoſed on the ſurface, waſhes away its virtues before vegetation is awakened by the ſun. But in July, if there be any ſhowers, the quick growth of the after-graſs will ſhelter and protect the manure; and nothing is to be feared but a ſevere drought. In this caſe, however, this after-growth ſhould be left through winter, to be fed in the ſpring, when the value of ſuch feed will be great, and the dung, by means of ſuch a covering will be guarded againſt the froſt in the beſt poſſible manner ‖.

Mr. Miller, however, reprobates the dreſſing of Graſs ground in ſummer, ſoon after the crop of hay is taken off the land: becauſe before Michaelmas the ſun will have exhaled moſt of the goodneſs, if the dreſſing be of dung, or any other ſort manure.

[It is moſtly the cuſtom to collect manure of every

deſcrip-

deſcription into one heap. Hence ſubſtances very oppoſite in their nature, and which may be wanted at different times and for different purpoſes, are laid together, and inſtead of forming a uſeful combination, perhaps prevent the dung from fermenting as it ought. Every farmer therefore ſhould have at leaſt two or three dunghills, to be prepared for uſe, according to the time at which the contents of each may be wanted, and the articles of which they are reſpectively compoſed.

If earth, moſs, ſhovellings of highways, &c. can be procured, the bottom of any dunghill compoſed of rank ſtable dung or ſhort exerementa dung may be laid three or four feet deep with theſe ſubſtances. This will increaſe the quantity of manure, for the moiſture that is preſſed out during the fermentation will ſink into the earth, &c. and impregnate it with its ſalts; and if the whole be afterwards turned and incorporated, what was laid in the bottom will be found of nearly equal value with the dung itſelf. See *Compoſt*.

Some diſtinctions are to be made reſpecting the different ſorts of Animal Dung.

Horſe-dung is more diſtinguiſhed for the readineſs with which it ferments, than for its intrinſic richneſs.]

Stable-muck, or horſe-dung mixed with ſtraw, properly fermented is of primary uſe in the kitchen garden, where it ſupplies the want of the ſun's heat in winter; affording at an early ſeaſon many eſculent plants which we could otherwiſe have only for a ſhort time in the middle of ſummer, and others which our moiſt and cold climate would not produce at all in any perfection. As Aſparagus, Cucumbers, Melons, Cauliflowers, Salad herbs, &c. &c. See *Hot Beds*.

Horſe dung is one of the beſt improvements for cold lands that can be procured in any quantity, yet alone, or when it is too new it is prejudicial to ſome plants; and if it be ſpread thin over lands in the ſummer time, it is of very little ſervice, becauſe the ſun draws out all the goodneſs of it, and it becomes little better than thatch or dry ſtraw. Although too much of it can ſcarcely be uſed in a kitchen garden, yet it may be a fault to lay too much on corn-land, becauſe it may be apt to make the corn run too much to ſtraw.

In very moiſt cold land crops will ſucceed better, if new horſe dung, as it comes from the ſtable, be buried in it, than if the ground be dreſſed with very rotten dung.

[Horſe dung, in a raw ſtate, is well calculated for Potatoes, becauſe it leaves room for the roots of that plant to ſpread. But if it be not fermented, it contains much undigeſted vegetable matter, and conſequently the ſeeds of many weeds which may have got into the food of the animal.

Cow dung is very uſeful for lean, dry, hot, ſandy or gravelly ſoils. The excrement of a ruminating animal is held to be preferable to that of horſes at graſs, owing to the quantity of animal juices mixed with their food in chewing: but ſince it does not contain much undigeſted matter it will hardly heat. The beſt way of managing it is to lay it together, and keep it moiſt till it is ſufficiently putrified.]

Being mixed with horſe dung it makes a good manure for moſt ſorts of ſoil, and with mud for ſome.

Sheep's dung and deer's dung differ not much in quality, and are eſteemed by ſome the beſt manure for cold clays. Some recommend them to be uſed as top-dreſſings to autumn and ſpring crops, four or five loads to an acre, in the ſame manner with aſhes, malt-duſt, &c. See *Folding* and *Top-dreſſing*.

In Flanders they houſe their ſheep at night in places ſpread with clean land, laid five or ſix inches thick, ſome being added every day, and the whole cleared out once a week. This mixture makes an excellent dreſſing for ſtrong, or cold ſtiff land.

[This method has been adopted in his Majeſty's farm at Windſor. In hard weather the ſtock is penned in a fixed fold, made large, and divided into two parts, pitched in ſome ſheltered ſpot, laid a foot thick with maiden earth, and daily littered with leaves, moſs, fern, ſtubble, &c. When the ſheep leave this fold, a layer of lime, chalk or peat aſh is put upon the top, and the whole being mixed together makes excellent manure for a Turnep crop. Six hundred loads of excellent compoſt have this been made in three months from ſix hundred ſheep[a].

In Holland Sheep's dung is carefully collected, cut into ſmall pieces, and ſold in baſkets at a high price.]

Hog's or *Swine's dung* is the fatteſt and moſt beneficial of all the animal dungs: one load, it is ſaid, will go as far as two loads of other dung. It is the beſt of all dungs for fruit-trees, eſpecially Apples and Pears in a light ſoil, and a very rich manure for graſs. Mr. Miller affirms that he has often uſed it to fruit-trees, when it was well rotted, and found it the moſt beneficial of any manure.

[In the opinion of Dr. Hunter, Swine's dung is the richeſt of the animal manures. It is commonly aſſerted that the dung is richer in proportion as the animal is fatter. Hence the ſuperiority of this dung. It is of an oily and ſaponaceous quality, and when applied with judgment is excellent for arable lands. It ſhould be uſed with caution on arable lands however, becauſe it is apt to be full of weeds.

Rabbet's dung appears, by an experiment of Mr. Arthur Young to be ſuperior even to that of Pigeons, and to laſt the longeſt[b]. But this experiment ſhould be repeated before we can give credit to what ſeems improbable.

Dung of Birds.

Pigeon's dung is certainly a rich manure, but not laſting; it muſt therefore be renewed the oftener. It is moſt applicable to cold and deep ſtiff land. Sometimes it is ſown upon wheat crops in the ſpring. It ſhould always be broke very ſmall, and ſown during moiſt weather, and if circumſtances will admit of its being harrowed in, ſo much the better. Poultry manure is of the ſame nature, and where it can be had in any quantity, is an excellent top-dreſſing, particularly for cold land. Columella ranks it next, in point of value, to the dung of pigeons.]

The dung of pigeons, poultry and geeſe, is alſo a great improver of meadow land; but before it is uſed, it ought to lie abroad ſome time, that the air may ſweeten it a little, and moliify the fiery heat of their dungs.

They ought to be dried before they are ſtrewed, being apt to clod in wet: and they ſhould be mixed with earth, ſand or aſhes, to keep them from clinging together, that they may be ſtrewed thin, being naturally very hot and ſtrong.

They are recommended as the beſt manure for Aſparagus, Strawberries, and any ſort of flowers; but for the latter they ſhould be be rotted and well mixed with earth.

They are ſaid to be good for trees whoſe leaves are apt to turn yellow: for this purpoſe they ſhould be ſpread an inch thick at the foot of the tree in autumn.

[Conſiderable quantities of valuable manure might be raiſed by thoſe who living near large commons keep great flocks of geeſe, if they were regularly houſed at night, and the place were littered with ſtraw, fern, ſaw-duſt, aſhes or ſand. The ſame advantage might be reaped by littering the places where other kinds of poultry rooſt. Every three or four weeks the places ſhould be cleaned out, and the dung laid in heaps to ferment, either alone or mixed with ſoil[c].

Human Ordure, *Night Soil* or *Privy Manure*, ſays Mortimer, is of all ſorts of dung the greateſt improver of land, eſpecially if mixed with other dung, ſtraw or earth to give it a fermentation, and to render it convenient for carriage. It ſells in foreign parts at a much greater rate than any other ſort of manure. In London it may be bought for 5s. a load.

Dr. Hunter affirms that it is the richeſt manure that can be introduced into the ſi-ld; that in Flanders they uſe it with great ſucceſs, either ſtrewed upon the land in the form of powder, or diſſolved in water and thrown on with a wooden ſcoop; but that it may be beſt prepared as a top-dreſſing by filling the pits of neceſſaries with earth or lime.

[a] Berks Survey. [b] North. tour 1. 129. Eaſtern tour 4. 341.
[c] Townley V. Ann. 1. 277.

In China and Japan wonderful attention is paid to faving this manure, which in thofe countries is preferred to all others, both on account of its richnefs, and its being free from weeds: infomuch that Chevalier Thunberg, the famous botanift, paffing through Japan with the Dutch embaffy, could fcarcely find any other plants in the corn fields but the corn itfelf. In thofe countries, the laws prohibit the wafte of human excrement, and every houfe has refervoirs for it, to the great annoyance of the traveller through their towns.

The illuftrious Swede's account of the procefs of manuring in Japan is worth tranfcribing. There is no part of the world, fays he, where manure is gathered with greater care than it is here, infomuch that nothing which can be converted to this ufe is loft. The cattle are fed at home the whole year round, fo that all their excrements are confined to the farm yards, and it is a common fpectacle to fee old men and children following horfes on the road with a fhell faftened to the end of a ftick, to collect the dung, which is carried home in a bafket. Urine is carefully collected in large earthen pots, which are funk in the earth here and there in different parts, not only in the towns but even befide the highways. The Japoncfe does not carry out his manure to be dried up in a fallow field by the fun, but gives himfelf the difguiting trouble of mixing up the various excrements of man and beaft, with water and urine, together with every kind of refufe from the kitchen: this he carries in two large pails into his field, and with a ladle pours it upon the plant, when it has attained the height of about fix inches, and receives the whole benefit of it, the liquor at the fame time penetrating immediately to the root. By this mode of manuring, and at the fame time by the farmer's indefatigable weeding, the fields are fo completely cleared of weeds, that the moft fharpfighted botanift would be fcarcely able to difcover a fingle plant of another fpecies among the corn*.

Mr. Young has found the effect of night-foil (from 160 to 320 bufhels on an acre) prodigious, trebling the produce on land unmanured: and he aflerts that in all the experiments he has made with this manure, he has found the refult almoft uniform. In a meadow lately laid down, and in very poor condition, two acres of the worft part being covered after hay-time with four waggon-loads of night-foil, unmixed with any thing and fpread directly, the herbage thickened furprifingly, and grew moft luxuriantly. The cattle, neglecting the reft of the field, were perpetually feeding on this part; fo that by autumn it was pared down like a fine green lawn, the other part being a dufky rough ragged pafture. The part of the field manured with night-foil continued excellent†.

How wonderful then does it feem that this manure has been fo neglected in moft parts of Europe, and particularly in England, where the greateft part of it is fuffered to run to wafte and poifon our rivers.

Lime thrown into the privy will make an excellent mixture with the excrement, and at the fame time take off the ill fmell and noxious vapours of it. Sawduft, peat-mofs, or any common earth will be highly ufeful in abforbing the urine. Lime will alfo render the excrement fo fhort and dry that it may be ufed as a top-dreffing.

Two cart-loads of ordure mixed with ten loads of earth and one of lime will be a fufficient top-dreffing for an acre, and is excellent upon light lands for wheat or barley: for the former of which it fhould be ufed early in the fpring; and for the latter it may be either fcattered upon the young crop, or harrowed in with the feed. It is particularly convenient for all drill crops.

Urine of every fort is found to be of great ufe when laid upon grafs or young crops early in the fpring. The moft convenient way of applying it feems to be in the form of a compoft, with earth and a fmall proportion of lime. In this fhape it is a good manure for moft foils, particularly fuch as are light, fandy or gravelly.

* Trav. vol. 4. † Annals, vol. 3 and 20.

Great quantities of this article might be faved, and judicioufly ufed would influre one or two good crops; about all farms and great towns it might be collected into refervoirs, with other excremental matters, without much trouble. In fome countries this is an object of police, efpecially in the towns, where refervoirs are eftablifhed for collecting it. The farmers carry it away in barrels, and either fpread it immediately upon their fields, or mix it into compoft*.

Mortimer obferves, that if Urine be deftructive to vegetables, it is the indifcreet ufe of it in too large a quantity; and that there is nothing which will improve land, or increafe the ftrength of manure, or help the fermentation of dung more than urine: for which reafon in Holland, they are as careful to preferve this as dung; and Mr. Hartlib in his legacy commends it as a great improver of land.

No ftable ought to be without a barrel or ciftern funk at the extremity of the paved channel into which the urine runs.

The rich juices of dunghills, fays Mr. Belcher, ought to be ftrictly attended to; for which purpofe layers of lime, chalk or its rubbifh, fhould be fpread under the litter in the farm-yard. Thefe are better than earth, which is apt to be poachy, unlefs of a very dry nature, fomething however fhould be laid to abforb the urine†.

The rich product, fays Mr. Young in one of his experiments, which attends the addition of urine to dung, affords a very important leffon; which is, to manage dunghills in fuch a manner, as to fave, if poffible, every drop: this is a point too much neglected, and indeed by moft common farmers very little attended to‡.

Bones, *Horns*, *Hair*, *Wool* and *Feathers*.

Bones are ufed as a manure, both by themfelves, and with other fubftances. The common way of treating them, is to break them with a mill, into pieces about the fize of a marble or nutmeg; they are afterwards laid upon the field in fmall heaps, at regular diftances, and covered with earth; after remaining in this ftate for fome time, they are fpread on fallows, on grafs, or on turnep land.

The conftituent parts of bones are oil, alkaline falts, and animal earth, united by fixed air. The oil is in much greater proportion than the alkali, which renders bones rather a heavy manure.

It does not appear that much pains is taken in adapting them to the foil for which they feem beft calculated, being laid indifcriminately upon lands of every defcription, and for the moft part unmixed with any other fubftance. But bones, being kept together by fixed air, unlefs they are either laid upon foils poffeffing principles that are capable of depriving them of this air, or have fomething of that kind previoufly mixed with them, the texture of their parts will remain unbroken, and they will be of little ufe. In Hertfordfhire however they are found to be an excellent manure for clay foils.

To render bones ufeful they fhould be ground as fmall as poffible. At Sheffield it is a trade to grind bones for the farmer, who will give 16d. a bufhel and fend fixteen miles for them. Some fubftance muft then be mixed with them that is capable of diflodging the fixed air, and diminifhing the principles contained in the bone. For this purpofe nothing will be found fo ufeful as quick-lime. Where there is no opportunity of grinding them, they may be mixed with lime in a heap, and will thus foon be reduced to powder. It is alfo a judicious practice to mix afhes with them; a cart-load to thirty or forty bufhels of bones, turning the whole when it has heated twenty-four hours, it may be laid on ten days afterwards.

Bones are fometimes burnt for the afhes, in this operation they are freed from the oil and mucilage, and are merely phofphoric acid united to lime or phoafate of lime: in this ftate they are merely a ftimulating manure. In their unburnt ftate they are both nutritive and ftimulating. Of all manures bone is

* Report on manures, 55. † Young's Ann. 2. 401.
‡ Ann. 9. 614.

perhaps the moſt permanent. What is here ſaid of bone in its recent and burnt ſtate, applies to horns, hoofs, wool, feathers and hair; like bone they conſiſt of phoſphate of lime, animal oil and mucilage.

When bones are uſed in their ſimple ſtate, without the addition of earth or lime, they ought never to be laid upon any but the ſharpeſt and moſt active ſoils; ſuch as limeſtone chalk or gravel: upon all theſe they will meet with more or leſs calcareous earth, which will in ſome degree diſengage their fixed air, and diſſolve the oil contained in them; but upon deep clays, tills or loams, they ſhould never be applied in that ſtate.

But when made into a compoſt, they may be applied with advantage upon ſoils of every deſcription, by laying it upon or near the ſurface, when the crop is in a growing ſtate. Upon wheat it ſhould be uſed early in the ſpring without harrowing; upon barley and oats it may be harrowed in along with the grain.

For drill crops, ſuch as turneps, beans, &c. they are particularly convenient, as they admit of being put into the drill at the ſame time with the ſeed, more readily than moſt other manures.

Dr. Hunter of York having laid down to graſs a large piece of very indifferent limeſtone land with a crop of corn, ſelected three roods, which he dreſſed with bones broken very ſmall, at the rate of ſixty buſhels to the acre. The crop of corn was greatly ſuperior to the reſt. The graſs next year was alſo ſuperior, and has preſerved the ſame ſuperiority ever ſince, inſomuch that in ſpring it is green three weeks before the reſt of the field.

He dreſſed two acres with bones in two different fields prepared for turneps, ſixty buſhels to the acre, and found the turneps greatly ſuperior to the others managed in the common way.

He dreſſed an acre of graſs ground, with bones, in october, and rolled them in. The ſucceeding crop of hay was an exceeding good one. However he has found from repeated experience, upon graſs ground, that this kind of manure exerts itſelf more powerfully the ſecond year than the firſt.

He recommends the bones to be bruiſed by putting them under a circular ſtone moved round upon its edge by means of a horſe, in the manner that tanners grind their bark.

To aſcertain the comparative merit of ground and unground bones, he dreſſed two acres of turneps with large bones in the ſame field where the ground ones were uſed. The reſult of the experiment was, that the unground materials did not perform the leaſt ſervice, whilſt thoſe parts of the field on which the ground bones were laid were greatly benefited.

All kinds of bones will anſwer the purpoſe of a rich dreſſing, but thoſe of fat cattle are the beſt. The London bones are frequently boiled, and muſt therefore be much inferior to ſuch as retain their oily parts.

Mr. Young however, in his experiments on manures, ſays that the effect of the London bones was ſo very great, that he bought all he could get at 10s. 6d. a waggon load of ninety-ſix buſhels in London. With a dreſſing of twenty-five cart loads the crop was ſuperior to that which had fifty. The land was a miſerable toil, which with a ſummer fallow yielded but thirty buſhels of wheat; but with a moderate manuring of bones yielded ſixty-three buſhels.

On barley he obſerves, that bones hold a moſt decided ſuperiority, and that expenſive as they are, they pay very amply.

Horns of every kind are an uſeful manure when cut into ſmall pieces; in their natural ſtate they produce little effect. The proportion proper to be employed varies with the ſize of the clips or ſhavings; fewer being neceſſary when ſmall, but the effect of the larger are longer felt. If they are of a middling ſize, about ſixty ſtones to an acre is a reaſonable quantity. It more be uſed, the grain is apt to be too luxuriant, and too long in ripening; it is alſo liable to be hurt by mildew.

The ſmall pieces are chiefly turner's ſhavings, are bought in London at 12s. or 15s. the quarter, and are much the moſt uſeful. The large ones are refuſe pieces of horn, coſt about 2s. leſs the quarter, and are generally ploughed in three months before ſowing wheat or barley. They both anſwer in moſt ſoils and ſeaſons, except very dry ones.

Hoofs are of the ſame nature with horn, and anſwer the ſame purpoſe.

Hair is likewiſe uſed with much the ſame effect. Hog's hair is ſometimes to be had in London at about 9s. the quarter.

Wool cannot well be applied as manure in its native ſtate; but very well after it has been wrought into cloth. See *Refuſe of Manufactures*.

Feathers would be a good manure, if they could be had in any quantity. A field being ready for ſowing wheat, one acre was manured with ten buſhels of old feathers procured from an upholſterer, ploughing them in as they were ſpread: the acre thus manured produced near forty-eight buſhels, and the other part of the field not twenty-eight buſhels on an average[a].

Fish, ſays Evelyn, is ſpread to great advantage on grounds, and for being quickly conſumed, may ſooneſt be applied. It is matter of ſurprize, ſays his annotator, that this hint given in 1675, ſhould have operated ſo little, that at this time (1778) the uſe of refuſe fiſh is hardly known. It is common however in Cornwall to manure with pilchards; about Leoſtoff with herring-ſcales; and whole barge-loads of ſticklebacks are ſometimes brought to Cambridge, and bought up by the farmers to lay upon their lands, as the whole neighbourhood can witneſs for a time from the intolerable ſtench with which they ſalute the noſtrils of the traveller.

The offal of fiſh would be worth attending to, eſpecially when they are cured in conſiderable quantities, as at Yarmouth, &c.

The proper way of uſing fiſh and its offal is to make it into a compoſt with other ſubſtances, particularly lime or chalk. Lay the fiſh in heaps for eight or ten days, till it begins to corrupt; then mix it with earth; in a fortnight turn the heap, and add one part of lime to three of fiſh; let this remain a month, turn it, and add as much earth as is equal in quantity to the whole heap of fiſh and lime.

Such a compoſt will be an excellent top-dreſſing for any crop. For wheat, early in the ſpring; for barley, either harrowed in with the ſeed, or applied upon the young crop. It is uſeful for drilled crops.

All *Recent Animal Subſtances*, as blood, and the whole refuſe of ſlaughter-houſes, ſhambles, &c. afford a very rich manure. Mixed with earth and freſh horſe-dung they make a very rich compoſt. Blood mixed with ſaw-duſt makes a good land-dreſſing to be ſown upon wheat in the ſpring. Blood is often recommended to be buried at the roots of fruit trees.

All *Putrid Animal Subſtances* are good manures if properly managed: when uſed alone they ſhould always be laid upon the moſt active ſoils, ſuch as chalk, limeſtone, &c. Upon ſtrong clays or deep loams they ſhould only be uſed in form of a compoſt.

The moſt proper way of preparing them for uſe, is to mix them with chalk or quick-lime, the mixture ſhould be laid in heaps of three or four cart-loads each, and covered with earth; after remaining in this ſtate for eight or ten days, the heap ſhould be turned over, and ten cart-loads of earth added to each cart-load of the mixture. It ſhould then remain for a month in the heap, and then may be applied as a top-dreſſing, or harrowed in with the ſeed.

All kinds of animal ſubſtances, when well digeſted and putrified, are the moſt powerful promoters of vegetation. In this ſtate almoſt the whole becomes volatile, and is ſo far attenuated, ſubtilized and refined, as to be rendered capable of entering the veſſels of the minuteſt plants. Inſomuch that it appears to ſome, that as the animal kingdom is ſupported by the vegetable, ſo the vegetable is by the animal; and that each is reciprocally the ſupport of, and is ſupported by the other[b].

[a] Bath papers, 1. 130. [b] Ibid. 3. 174.

REFUSE OF MANUFACTURES.

Under this head a variety of articles may be enumerated:

Fellmonger's cuttings or *Pooks*, uſed in Surry and Kent and about Dunſtable. Compoſed of ſheep's trotters, hair, ſcrapings of the pelts, lime, &c. There are two ſorts, the white and the brown; the white is much the beſt, having more oil, lime and hair in it, but they are both good, and go farther in dreſſing land than almoſt any manure, in the proportion of four to one. About Dunſtable the price is 6d. a buſhel, and they uſe from twenty to forty buſhels an acre.

Furrier's clippings, bought in London at 12s. or 13s. the quarter, weighing about two hundred weight and a half. They are ſown by hand from the feed-ſcuttle on land intended for wheat or barley, and immediately ploughed in; the pieces that are left above ground are pricked in by a ſtick, to prevent their being devoured by dogs or crows. From two to three quarters are uſed on a ſtatute acre. They anſwer well on light dry chalk or gravelly ſoils, where they hold moiſture, and help the crop greatly in dry ſeaſons.

Refuſe of Hair manufactures.

Horn ſhavings. Already mentioned.

Glue-maker's refuſe. A very ſtrong manure.

Rags. Woollen rags in London are from 3s. 6d. to 4s. 6d. the hundred weight (in Berkſhire about 5s.) or about 4l. 17s. the ton. Being generally in large pieces they are chopped ſmall, about an inch or two ſquare. They are ſown by hand, and ploughed in three months before ſowing wheat or barley, and the quantity uſed is from ſix to ten hundred weight on a ſtatute acre. If with dung, three hundred weight.

Mortimer ſays they are a great improvement of chalky binding lands; that in his time many loads were fetched from London to Dunſtable; that they coſt 4d. a buſhel in London; that they chopped them ſmall and ſowed them juſt after the ſowing of the corn, allowing four ſacks (of ſix buſhels each) to an acre.

Woollen rags hold moiſture, and are adapted to dry, gravelly and chalky ſoils; and ſucceed in dry ſeaſons better than moſt manures; but do little good on wet ſoils. London rags are beſt; but the danger of catching the ſmall-pox in chopping and ſowing them deters many farmers from their uſe.

In Berkſhire they are uſed for dreſſing wheat and clover-leys, and even upon light ſoils produce abundant crops. They are ſaid to produce very ſenſible effects five or ſix years after they are laid on, and to be better the ſecond or third year than the firſt.

In Northamptonſhire they are found to anſwer well as a preparation for barley.

Scrapings of oiled Leather.

Shoemaker's Chips.

Soaper's Aſhes, Soap-boiler's Waſte, or Aſhlep is much commended as a manure both for corn and graſs by Sir Hugh Plat. It contains fifty-ſeven in the hundred of mild calx, eleven of magneſia, ſix of argil, and twenty-one of ſilex.

The effect on cold ſward is ſaid to be very great. Mortimer ſays, he was told of one by Ware, who had a piece of land run over with broom and furze, which he manured with ſoap-aſhes, and ſowed ſix years together with wheat, and had incredible crops. An Eſſex farmer, in the Bath papers (1. 129.) informs us, that in april he top-dreſſed half a field of clover with ſixty buſhels to the acre of this manure, and that this half produced near double the quantity of hay that the other did. He alſo uſed it with great ſucceſs on cold wet ſpongy meadow-land. It apparently dried it, and made it produce much greater crops of graſs.

Sugar-baker's ſcum. To be had from 5s. to 7s. 6d. a load.

Tallow-chandler's refuſe, called *Graves*.

Refuſe of Potteries, as a top-dreſſing for graſs, on a clay ſoil. The riddlings of half-burnt coals and earth from the kilns: which would have nearly the ſame effect as common coal-aſhes. Worn-out moulds of plaiſter of Paris powdered, might anſwer as gypſum.

Refuſe of Alum-works; called *Slam* in Yorkſhire. Uſed with ſea-weed, lime, &c. to make a compoſt.

OIL, *Oil-cake* or *Rape-cake* and *Oil-Compoſt*.

Freſh oil alone, ſo far from being a manure, is a poiſon to vegetables. Mixed however with lime or alkaline ſalts it becomes the richeſt of manures, being thus made miſcible with water. Or made to putrify with animal or vegetable ſubſtances, it will become a manure.

Oil-cake or Rape-cake has long been uſed as a manure in Norfolk. Being ground, or broken into ſmall pieces, it is ſown by hand out of a common ſeed-box, upon the laſt ploughing but one of a ſummer-fallow for wheat. Alone it anſwers beſt on chalky and limeſtone ſoils; on heavy loams and clays, much of it will remain inactive, unleſs it be mixed with lime, &c. If it be intended for a hand-dreſſing, ſix parts of rape-duſt and one of lime will make an excellent compoſt, for ſoils of every deſcription. The lime ſhould be mixed with the rape-duſt at leaſt ten days before it is uſed, and turned every day. It may thus be applied to wheat as a top-dreſſing in the ſpring.

On calcareous ſoils it may be uſed without lime. On thin limeſtone at a diſtance from dung this is an invaluable manure, at the rate of three quarters an acre for barley, and four for wheat, ſown by hand, and harrowed in with the grain: if rain fall within a week or ten days after ſowing, the crop is generally good; but if no rain fall till long after, it is but little benefited by this expenſive dreſſing; nor is the crop of the ſucceeding year benefited by it.

The price of this manure advancing ſo much in price as to render it doubtful whether it will anſwer to the farmer, Dr. Hunter has invented an oil-compoſt that comes cheap, and is of eaſy carriage. It is made of American pot-aſh, twelve pounds broken into ſmall pieces, and put into a convenient veſſel with four gallons of water. When it has ſtood twenty four hours, add of coarſe train-oil fourteen gallons. In a few days the ſalt will be diſſolved, and the mixture upon ſtirring will become nearly uniform. Then take fourteen buſhels of ſand, or twenty of dry mould; upon theſe pour the liquid ingredients. Turn the compoſition frequently over, and in ſix months it will be fit for uſe. The above quantity is ſufficient for an acre.

For the convenience of carriage no more earth is here directed to be uſed than will effectually take up the liquid ingredients. But if the farmer chooſes to mix up the compoſt with the mould of his field, he may uſe a larger portion of earth, by which means he will be enabled to diſtribute it with more regularity upon the ſurface.

This oil-compoſt is only intended to ſupply the place of rape-duſt, ſoot, woollen rags, and other expenſive hand-dreſſings. It is in all reſpects inferior to rotten dung; where that can be obtained, every kind of manure muſt give place to it. For at the ſame time that dung affords nourithment, it opens the pores of the earth: whereas hand-dreſſings give food to plants, but contribute nothing towards loofening the ſoil. This is an uſeful and practical diſtinction.

How different is the language of the philoſopher from that of the empiric, whoſe noſtrum is adapted to all caſes and purpoſes, and is ſuperior to all others in every thing!

Dr. Hunter recommends it, but with the diffidence of a true philoſopher, who depends ultimately upon experience, to be ſown immediately after the grain, and both harrowed in together.

He thinks it will anſwer beſt for winter crops: for from the unctuouſneſs of its nature it is more than probable that it ſhould lie expoſed for a long time to the influence of the weather; which benefit it is deprived of when uſed for barley, and ſuch crops as are ſown late in the ſpring. For this reaſon the compoſt upon turneps has proved generally unſucceſsful: but then thoſe parts of the field on which it had been ſpread produced the beſt crops of grain the following year. From this ſlow manner of giving out its virtues, it ſeems to be an improper dreſſing for all plants that have a quick vegetation.

Georg. Eſſays. 2

All lands that have been exhauſted by frequent crops, are robbed of their oily particles, and thus become barren. The oil-compoſt, by plentifully reſtoring particles ſimilar to thoſe which have been carried off, ſhould ſeem to be a proper reſtorative. To lands under ſuch circumſtances, lime is the worſt manure that can be applied [x].

Dr. Hunter has followed up his theory with experiments. For corn and horizontal feeders he recommends it to be ſown upon the ſurface with the hand: for cabbages, hops, beans, carrots and all tap-rooted plants, it is beſt to be worked into the ſoil by the plough or ſpade. When diſtributed upon the ſurface it is ſoon meliorated by the action of the air, rains and dews: but when worked into the ſoil it is deprived of thoſe neceſſary influences.

Some injudicious enquirers have placed a handful of the compoſt cloſe to the roots of a cabbage plant: hence death or a feeble vegetation enſued; and an argument was raiſed againſt the nutritive power of the compoſt. Lime, the aſhes of burnt vegetables, ſtale urine, gooſe and hog dung, when improperly applied, are all poiſons [y].

Chriſtopher Baldwin, Eſq. of Clapham-park, Surry, purchaſed ſixty gallons of the bottoms or foots of oil, and a rich thick South Sea whale oil at 14d. the gallon; and having made a bottom of twenty loads of mould, with eight loads of dung on it, he carried on three loads of light ſandy mould, and one load of brick and mortar rubbiſh ground fine; having mixed theſe well, he made a kind of diſh of it about five feet wide and ten feet long; into this he put half the oil, in auguſt: the heat of the ſun ſoon made the thick oil ſink into the compoſt, when it was directly thrown up into a heap, broke down again, and by five or ſix turnings well mixed together, and left in a heap two days, when it was ſpread equally over the whole dunghill; twenty loads more of good mould were then carried on, eight loads of dung, and the remaining thirty gallons of oil were mixed as before in ſandy mould and mortar rubbiſh, and equally ſpread over, and the whole was covered by trimming the four ſides of the dunghill, and throwing it on the top.

Thus it lay more than two months, when it was cut down by mattocks, carefully broke, well mixed and turned over. The end of march it was carried on a five-acre field, ſpread and ploughed in: it lay a fortnight, the land was then ploughed again, and on the 22d of april the field was drilled with barley, two buſhels to an acre. The crop was ſixty buſhels on an acre, of the beſt quality: five quarters were ſent into Norfolk for ſeed-barley, under the denomination of fifteen coomb barley; and it weighed 220lb. the ſack, or 55lb. the buſhel, Winchester meaſure.

This barley followed oats upon a lay of ſix years old. The oats ſuffered much from the wire worm, which this manure completely deſtroyed; the barley not ſuffering from it in the leaſt.

Mr. Baldwin uſed this oil-compoſt with ſucceſs on ridges of ſummer cucumbers, and on cabbages [z].

Mr. Baldwin had not the ſame ſucceſs in Hampſhire on a ſix-acre piece of ſtrong land, with large ſtones, very poor, that had never been dunged. Five acres were chalked and the whole was ſown with oats. December following it was ploughed. In january the oil-compoſt was carried on that part of the field which had not been chalked, and over half an acre of the chalked part; the remainder was dunged. In february it was ploughed; and in march drilled with hog peaſe. The chalked part was the beſt; the unchalked part, where the oil manure was put, though good, was not to compare to the chalked part: and the half-acre chalked and oiled, appeared no better than the dunged part [a].

Dr. Wilkinſon of Enfield uſed Dr. Hunter's oil-compoſt, as a top-dreſſing, in ſpring, on two acres of wheat, the ſoil a pebbly loam on a gravelly ſubſoil, very poor, and never remembered to have borne a crop of wheat. The produce however was nearly three quarters to an acre. The ſtraw was ſhort and light, but the ear was full and heavy. The quantity of manure to an acre was 12lb. of pot-aſh diſſolved in four gallons of water, and mixed with twenty buſhels of dry mould, and fourteen gallons of train oil.

This gentleman tried the ſame quantity of this manure on two acres of turneps; the ſoil a wet loam on a clayey bottom. It was all dreſſed with twelve loads an acre of rotten dung. When the turneps were ſown, the two acres had an additional covering of the oil manure. The whole crop ſuffered from the fly, but the part where the oil had been laid recovered the ſooneſt. The two acres retained their ſuperiority, and the eye could eaſily trace where the oil had been laid by the more luxuriant vegetation [b].

A Norfolk gentleman farmer recommends an oil-compoſt of materials different from Dr. Hunter's. Of rape or train-oil ſix gallons. Sea-ſand ſix buſhels. Coarſe ſalt two buſhels. Malt-coombs twenty-four buſhels. Spread the coombs on the floor four inches thick; ſprinkle the ſalt level; throw on half the quantity of ſand, and half the quantity of oil out of a watering-pot; turn it and rake it well: add the reſt of the ſand and oil; turn it well till thoroughly mixed, and then throw it in a heap for uſe. The ſand and ſalt not only occaſion it to imbibe the oil more freely, but give it a better body for ſpreading on the land [c].

Sea Weed, *Ware* or *Ore*, is uſed as a manure upon almoſt every part of the coaſt where it can be obtained in ſufficient quantity. In ſeveral parts of the kingdom the value of land has increaſed ſix-fold from the circumſtance of the proprietor or occupier having eaſy acceſs to it. Upon lands ſituated on a dry lime-ſtone bottom, it has produced the moſt ſurpriſing effects.

The ſea-weed commonly uſed in Scotland is of three different ſorts. The beſt is that which is cut from the rocks, and of which kelp is made. The ſecond is called the peaſy ſort. The worſt is that with a long ſtalk. The common practice is to ſpread the weed immediately after it is brought from the ſhore, either upon the ſtubbles or graſs lands. When laid upon the ſtubbles it is generally ploughed in as ſoon as poſſible. Farmers who can uſe it freſh do not lay it in heaps to ferment, becauſe a load of freſh ware will be of more ſervice freſh than two loads laid in a heap to ferment.

In moſt caſes ſea-weed may be conveniently uſed in this way, for where a farm is under a proper rotation there will always be ground to lay it upon. During the winter months it may be put upon the ley and ſtubble fields, in the ſpring upon the bean and barley lands; during ſummer the fallows will require all that can be collected; and by the time theſe are ſufficiently manured, the clover fields after the firſt cutting will be ready to receive the remainder; through the autumn the ſtubble fields will require all that can be collected. Thus throughout the year this valuable manure may be uſed as ſoon as it is thrown upon the beach, and experience proves that its greateſt value is in that ſtate.

If however more weed is thrown out than can be conveniently uſed, it is an object of importance to preſerve its qualities as much as poſſible. This is beſt done by making it into a compoſt with earth and a ſmall proportion of lime. If the quantity of earth be great enough to abſorb and retain the juices and ſalts of the ſea-weed, the proportion of lime moderate, the whole well incorporated and protected from heavy rains, it will be found nearly as valuable as in a freſh ſtate.

After the compoſt is properly mixed lay it up in form of a ridge with a pretty ſharp angle at top, covered two or three inches with earth, well beat with the back of a ſpade, and defended from the rains with ſtraw.

This compoſt will be found a good dreſſing for young crops of every deſcription, and may be uſed either at the time of ſowing the grain, and harrowed in along with it, or after the plants have made ſome

[x] Georg. Eſſay, p. 32, 35, 36. [y] Ibid. p. 4.
[z] Young's Ann. 15. 502. [a] Ibid. 15. 350.
[b] Young's Ann. 15. 341. [c] Bath papers, 1. 149.

progreſs.

progreſs. Upon wheat it ſhould always be uſed to the young crop early in the ſpring. Upon rich deep land it is bad huſbandry to lay ſea-weed or indeed any heavy rich manure; lime, chalk, ſhells, &c. are the proper ſubſtances. This manure ſeems peculiarly adapted to lands that have been hurt by over-liming; the bad effects of which it will more readily correct than any other except oil and animal ſubſtances.

In the neighbourhood of Berwick ſea-weed is uſed in their compound dunghills, with fold-yard dung, ſtable-dung and earth; and thus an immenſe quantity of manure is produced by ſuch farmers as are ſituated near the ſea. Such as uſe the ſea-weed properly, have their lands in ſuch heat as ſeldom to have occaſion for a fallow. This ſpecies of manure is found to be excellent for gardens, as it not only enriches the ground, but alſo deſtroys all kinds of inſects [d].

Sea-weed is much uſed on the coaſt of Norfolk and the eaſtern coaſt of Kent. It is mixed with dung and mould, and after turning ſeveral times over, ſpread on corn land [e].

Much ſea-weed is collected in the Iſle of Thanet at a conſiderable expenſe for manure, which is generally put between layers of dry farm-yard dung and hedge-mould: the moiſture from the ſea-weed contributes to the well rotting of the mafs, and has been the means of making poor barren chalky lands produce excellent crops of barley, ſeeds and wheat. The farmers are ſo very attentive to get the weed the inſtant it comes on ſhore, that the men and carts go in the middle of the night to fetch it up the gate way; and ſometimes even leave off all hands in the height of harveſt to get it, when it comes aſhore at that time [f].

In Cornwall, ſays Mortimer, is a weed called *Ore-weed*, which grows upon rocks under high-water mark, and ſome is broken from the bottom of the ſea by rough weather, and caſt upon the ſhore by winds and floods, with which they improve their barley lands.

Sea-ore being laid on a field, which from its ſterility had obtained the appellation of Starve-lark, in the month of march, it was immediately ploughed and ſowed with oats: the produce exceeded five quarters on an acre. It was ſown again, and the crop of oats exceeded any thing that had ever been ſeen on the land [g].

Ore is probably the ſame word with *Ware*, which being pronounced as we commonly do the word *War*, is not very different from *Ore* or *Orr*.

River Weed. In ſummer great quantities might be gathered, in lakes, in rivers where the water is deep and has no current, and in all wet ditches. Its effects upon wheat and other grain, as well as upon turneps, cabbages, and other green crops are well aſcertained. It may be laid on the land green and ploughed in, or it may be mixed with earth and dung.

The beſt way of preparing it for manure is to let it lay in ſmall heaps for a day or two, to drain off the ſuperfluous moiſture. It may then be put into large heaps of three or four cart-loads each till the fermentation is over; each heap ſhould then have three times the quantity of earth or mud mixed with it. Incorporate them well, and let them remain for a week or ten days; turn them, adding at the ſame time a quantity of hot new-ſlacked lime. This compoſt will be ready for uſe in a month.

Mortimer ſays, that *Snad-ced* or *Snag-gret* lies frequently in deep rivers, and is full of little ſhells; one load of which is reckoned as good as three loads of dung.

I take this to be what botaniſts call *Chara*.

A conſiderable quantity of river-weed being laid on the bank to drain and ferment, ſhrunk to one-third of their firſt bulk, and underwent a high putrefaction, breeding an amazing variety and multitude of inſects. In this ſtate they were carted on two ſmall pieces, together about two acres and a half, that had been folded for wheat. The crop on that ground had evidently the ſuperiority in groſſneſs and colour. Cattle were fond of eating them [h].

[d] Georg. Fil. 4. 207. [e] Bath papers, 1. 209.
[f] Young's Ann. 19. 84. [g] Ibid. 7. 39. [h] Ibid. 8. 32.

River-weeds being put in to every furrow that was at the next turn filled up by the plough, on one acre of a piece deſigned for turneps; by the moiſture and fermentation of the weeds the ſeeds vegetated much ſooner than on the reſt of the field, which was manured in the common way. They alſo grew quicker, and were ſuperior both in the ſize of the roots and luxuriance of the leaves, ſo as to render the ſpot very conſpicuous in the field. But in the ſucceeding crop of barley there was a manifeſt inferiority in this piece to the reſt of the land.

River-weeds being ploughed in at the end of october on part of a peaſe ſtubble, and wheat ſet by hand upon it, the whole field was a good crop, and the part on which the weeds were laid not at all inferior to the reſt, on which ſtable-dung had been ſpread in the uſual mode [i].]

Other Weeds.

Rotten vegetables of moſt ſorts will enrich land. Not only the weeds of ponds, lakes, rivers or ditches, but any other ſorts of weeds, laid in heaps to rot, will make good manure: ſuch as the weeds that too frequently diſgrace the headlands and balks of arable lands, commons, &c. the refuſe of kitchen gardens, &c. Whenever any weeds are uſed for the purpoſe of manure, they ſhould be cut down as ſoon as they begin to flower; for if they are ſuffered to ſtand till their ſeeds are ripe, the land will be ſtored with weeds, which cannot eaſily be deſtroyed: nay ſome kinds of weeds, if they are permitted to ſtand ſo long as to form their ſeeds, will perfect them after they are cut down. The ſureſt method therefore is to cut them juſt as they begin to flower, when they are in the greateſt vigour, and fuller of juice than when they are farther advanced. In rotting theſe weeds, it will be proper to mix earth or mud with them, to prevent their taking fire, as they are apt to do when laid in large heaps. When they are well rotted, they form a ſolid mafs, which will cut like butter, and be very full of oil.

Fern mowed whilſt it is green and tender, and laid in heaps to rot, will make a good manure. [Or it may firſt ſerve the purpoſe of litter in the ſtable or yard, and thus increaſe the quantity of dung.

This, with thiſtles and other large weeds, may be laid in heaps and burnt to great advantage; the aſhes being an excellent top-dreſſing for any crops.

Mud whether from the ſea, rivers or ponds is an excellent manure on any ſoil, both alone, and with lime, &c. Its greateſt value is upon thin ſoils, the fertility of which it increaſes amazingly, at the ſame time adding to the ſtaple of the land.

All manner of Sea-Ouſe or Ouſe mud, ſays Mortimer, and the mud of rivers, lakes, or the bottom of ditches, the waſh of paſtures, fields, commons, roads, ſtreets, or back-ſides in any place where water meets with reſt, or that rain-water has a long time ſettled, or that links run into, are of very great advantage to all ſorts of land, eſpecially dry gravely or ſandy, and are mixed with dung.

The ſcouring of old ditches, the mud of ponds, and the ſediment of all ſtagnant waters are particularly excellent upon graſs land. Maiden earth, with one-ſeventh of lime, and another ſeventh of rotten dung, added to it, will make it very proper manure for moſt kinds of paſture [k].

Mud ſhould not be laid on freſh, or as ſoon as it is dry, but it ſhould be well turned over and fermented with dung, or mixed with lime, to make the ſeeds in it vegetate, or to deſtroy their vegetation. Innumerable ſeeds fall or are carried into the water, ſink to the bottom, and not being aquatics, if they have much oil in them, are embalmed in the mud for years or ages, to vegetate whenever they ſhall happen to come within reach of the atmoſphere in a proper matrix.

It may be dug between hay time and harveſt, and either made into a compoſt when dry, or being turned over and levelled, and expoſed to a winter's froſt, may be dug in ſpring and planted with potatoes.

When

When this crop is cleared, it may be carted upon paſture, and will produce a luxuriant crop of graſs [1].

In Yorkſhire and Lincolnſhire they have what is called Warp land, or lands enriched with the ſediments of rivers or arms of the ſea, when the banks are overflowed. This generally takes place in the winter or early in the ſpring: they cannot therefore ſow wheat, but great crops of ſpring corn are raiſed.

In Cheſhire, the ſoil depoſited at the extremity of ſalt-marſhes, commonly known there under the name of *Sea-ſludge*, after it has been graſſed over for a few years, is ſaid to be the moſt productive and laſting of any ſort of manure, containing all the ſtrength of marl and the richneſs of black dung.

Many of our river's mouths would doubtleſs ſupply, in an inexhauſtible abundance, a ſaponaceous ſilt impregnated in ſome degree with ſalt, which would be an admirable manure [2].

Sweeping of Streets.

This is a mixture of moſt ſubſtances valuable in agriculture, and needs the aſſiſtance of fermentation leſs than any of them to render it fit for uſe; being made up principally of the offal of houſes, dung of horſes and cattle, aſhes, &c. It may be either ploughed in as dung, or uſed in the ſpring to invigorate wheat that is weak from not having been ſufficiently manured or from any other cauſe. It may be employed in general as a top dreſſing, or put into the furrow with drilled crops.

Sweepings of Roads.

The dung and ſand ſwept up, or dirt ſhovelled up on turnpike roads, would make an excellent manure, and at the ſame time remove a great annoyance to travellers. Where roads are made with limeſtone, this manure will be particularly valuable; and where they are made with flints it anſwers for graſs land.

Rubbiſh of Buildings, Walls, &c.

The backs of ditch-banks, the borders of fences in general, the ſides of lanes, and the nooks of yards, &c. &c. which are ſuffered to remain, from generation to generation, the nurſery of weeds, turned up into ridges, to rot the roots, &c. make an excellent manure. As does alſo the rubbiſh of old buildings, called in Norfolk *merryin*. Sea-ſtone walls afford a great quantity of this valuable article; which, from its immediate effect and duration jointly, is conſidered by ſome as ſuperior to marl, mould, or even dung itſelf, eſpecially upon ſcalds and hot burning ſoils. It is ſometimes mixed with dung, but more commonly ſet on alone [3].

The rubbiſh of old lath and plaſter buildings is incomparable manure for clover leys or graſs lands two loads to an acre. It is ſaid to laſt twenty years [4].

Lime-rubbiſh is uſed by gardeners to bottom gravel-walks, to mix with earth for tulips, &c. and to plant vines and figs.

Mud or earth walls acquire conſiderable fertility, and as they moulder, or fall away become uſeful in the compoſt dunghill.

Malt-Duſt, *Comb* or *Coombs*.

This is reckoned one of the moſt efficacious manures. It is the duſt that ſeparates from the malt in the act of drying; and is uſed as a top-dreſſing for barley, for clover, turneps, &c.

Mortimer ſays it is a great improver of barley, allowing forty buſhels to an acre, but that it laſts only one crop.

A piece of land being manured with malt-coombs, at the rate of four quarters to the acre, and ſowed with clover and barley; the barley produced near ſeven quarters on an acre, and the crop of clover was one of the fineſt that ever was ſeen [5].

About Dunſtable malt-duſt coſts 1s. a buſhel. It is ſown by hand, from twenty-four to thirty-two buſhels on an acre, at the ſame time with barley, and harrowed in with the ſeed. It ſuits moſt ſoils and ſeaſons; but quickly ſpends itſelf, and is therefore never ſown with wheat. As a top-dreſſing to wheat in march, about thirty buſhels to an acre, it probably would ſucceed. Black malt-duſt, or ſuch as falls through the kiln-plate in drying, is greatly preferred to the white, on account of the ſeeds of charlock, with which it abounds being deſtroyed by the heat [6].]

Mr. Miller ſays, it is a great enricher of barren ground, having a natural heat and ſweetneſs in it, which imparts to the ſoil a proper fermentation, eſpecially where grounds are a natural clay, and have contracted a fourneſs and auſterity, whether from having lain long untilled and unexpoſed to the air, or from water having ſtood long on them.

Oak Bark or *Tanner's Bark*.

Oak bark, after the tanners have uſed it for tanning leather, when laid in a heap and rotted, is an excellent manure, eſpecially for ſtiff cold land; in which one load of this manure will improve the ground more, and laſt longer, than two loads of the richeſt dungs; and yet it is very common to ſee large heaps of this remaining in the tanners yards for many years, in ſeveral parts of England, where manure of other kinds is very ſcarce, and often carried to a great diſtance. Of late years this has been much uſed for hot-beds in ſeveral parts of England, and is found greatly to exceed horſe-dung for that purpoſe, the fermentation being moderate and of long continuance; ſo that a bed of tan, when rightly made, will continue in a moderate temperature of heat for three or four months; and when the heat begins to decay, if it be ſtirred up with a dung fork, and ſome freſh tan added to it, the heat will renew again, and laſt for ſome months, ſo that theſe beds are by far the moſt kindly for exotic plants; and whatever plants are plunged into theſe beds, if they are permitted to root the bottom of the pots, they will thrive more in one month after, than they did in four months while they were confined to the pots. Many plants that root through the pots into the tan, ſend forth roots upwards of twelve feet each way in leſs than three months, and the plants advance in proportion.

After the tan is uſed for a hot-bed it may be ſpread on the ground for manure, and will greatly enrich it: but it is beſt for cold ſtrong land, becauſe it is of a warm nature, and will looſen and ſeparate the earth. When this manure is laid upon graſs, it ſhould be done ſoon after michaelmas, that the winter rains may waſh it into the ground; for if it be laid on in the ſpring, it will burn the graſs, and inſtead of improving will greatly injure it, at leaſt for that ſeaſon. Where it is uſed on corn land, it ſhould be ſpread on the ſurface before the laſt ploughing, that it may be turned down for the fibres of the corn to reach it in the ſpring: for if it lies too near the ſurface, it will forward the growth of the corn in winter; but in the ſpring, when the nouriſhment is chiefly wanted, it will be nearly conſumed, and the corn will receive little advantage from it. Nor will it be proper to have this manure lie too near the roots of any plants, for when this happens it is prejudicial to moſt of them, but eſpecially to bulbous and tuberous-rooted flowers. But when it is buried juſt deep enough for the fibres of the roots to reach it in the ſpring, the flowers have been exceedingly improved by it: and in ſome places, where this manure has been uſed in kitchen-gardens, it has greatly improved the vegetables.

[In proceſs of time tan is certainly converted into vegetable mould. When it becomes rotten and is ſpread pretty thick, it has been found of great uſe to graſs ground. But the moſt likely method of rendering it uſeful is to mix it with lime, or perhaps with ſalt. Or after it is taken out of the tan-pit, and waſhed, mix it with an equal quantity of freſh horſe-dung, including the litter, and cover it from rain, but let the whole be kept moiſt. When the heat is gone off, mix it with a freſh quantity of horſe-dring, to renew the heat: when that is gone off, the whole being made into a compoſt with chalk, will form a very enriching manure.

[4] Young's Ann. 5. 360. and 18. 433.
[5] Bedford in Bath papers, 3. 300.

Two waggon loads of tan from the tanners, with one waggon load of unſlaked lime, mixed together, and lying for a week, being uſed as a top-dreſſing for turneps and graſs, was found to be excellent for both.

Mortimer mentions a piece of land in Cumberland of two acres and a half, let for 11l. annual rent. What improved it to that value was the emptying of the town tan-pits on it.

Soot is uſed as a manure in almoſt every part of our iſland, where it can be procured in ſufficient quantities, and is applied in every different ſhape, and to all crops. In the language of the chemiſts, it is a ſublimate, conſiſting principally of carbon in a moſt ſubtile powdery ſtate, and ammoniac or volatile alkali. Whether the carbon can be obſerved, is an undecided queſtion; but the volatile alkali operates as a ſtimulant, and it may even prove nutritious; for it conſiſts of hydrogen and azote.

Uſed in its ſimple ſtate, it anſwers beſt upon light gravel, chalk or limeſtone ſoils: if in a compoſt, the proper proportions are, two loads of ſoot, the ſame quantity of lime, and ten loads of earth. The ſoot and earth ſhould be well incorporated, and remain in a heap a week or ten days, then turned, and the lime added in ſtratums as it is turned over; in this ſtate it may remain a month or ſix weeks, and be again turned, taking care to break every part of it as ſmall as poſſible, by working it well with the ſpade: in a week or two more it will be ready for uſe. This compoſt may be employed upon every ſort of grain, eſpecially wheat or barley; and if rain fall ſoon after it is laid on, it will immediately begin to operate.

Soot, ſays Mortimer, is very good both for corn and graſs, eſpecially on cold clays or lands much overrun with moſs: but ſea-coal ſoot is the beſt by much: forty buſhels are commonly allowed to an acre, but ſome lands require more. A hundred buſhels have produced an extraordinary crop; but it was a dry ſeaſon: if much rain had followed, being laid on ſo thick, it might probably have diſſolved the roots and ſtalks of the plants entirely. If the weather prove dry, a ſmall quantity has little effect, being evaporated or diſperſed by the ſun and winds.

About Baldock, they bring ſoot from London, three hundred buſhels to a waggon load. The price is from 7d. to 9d. a buſhel, very ſhort meaſure, which makes the price from 9d. to 11d. the Winchеſter buſhel ſtruck. It is laid on a heap on the lands. From this a common feed-ſcuttle is filled, and a man walking the length of the lands ſows the ſoot as they do corn. The quantity uſed on a ſtatute acre is from twenty to forty Winchеſter buſhels. In general, thirty buſhels are reckoned a complete dreſſing, when dung or other manure has not been uſed: but when the land has been dunged, half the quantity of ſoot is ſufficient. Soot is found to anſwer beſt on wheat in april. It likewiſe ſucceeds on peas or clover in the ſame month; and has a good effect ſown with barley in the beginning of april, and harrowed in. A ſlight dreſſing of ſoot is uſed at any time in the ſpring, when grubs or worms appear to injure the young corn. Thinly diſtributed on newly ſown turneps, juſt before they come up, it prevents the fly or grub from injuring them, provided no rain falls to waſh it into the ſoil; but if ſown after the plants come up, it greatly injures them, particularly if the ſeaſon comes dry.

Soot anſwers beſt on light dry chalk ſoils, and in moderately wet ſeaſons: it does little good on ſtrong or wet land, or in very dry ſeaſons, unleſs ſown earlier than uſual. The London coal-ſoot, is generally mixed with cork-duſt, coal-aſhes, or ſweepings of the ſtreets; yet even in this adulterated ſtate, it is found to anſwer much better than country ſoot from wood[*].

In Norfolk, near towns, ſoot is uſed as a top-dreſſing for wheat in february or march. If it be ſown early, and the froſt catch it, the ſtrength is thereby lowered: if late, and no rain fall to waſh it in, it is thought rather injurious than beneficial. And it is not, in any caſe, found of much, if any, ſervice, to the ſucceeding crop of barley. The quantity ſet on is forty buſhels an acre.

Their manner of ſowing it is this. A favourable opportunity being embraced, when the wind blows gently in the direction of the lands or ridges; the waggon, which is kept under cover till wanted, is drawn in a furrow againſt the wind; while a man, ſtanding on the outſide of the waggon, ſpreads the ſoot with a ſhovel, ſeveral yards wide, on either ſide of him; the height of his ſituation at once enabling him to ſpread it wide and even. As he reaches the windward end of the lands, the team wheels round under the hedges, and takes a freſh width'.

Soot is an excellent manure for paſture land, in the quantity of forty buſhels to an acre. Mortimer ſays, it produces a mighty fine ſweet graſs, and deſtroys weeds and trumpery.

Lucerne is much improved by it. It is the favourite manure for Sainfoin on the downs of Wiltſhire; only ten buſhels on an acre: and is in general reputed good for this graſs.

It is commonly reputed to deſtroy clover, while it encourages the growth of ray-graſs. Dr. Anderſon informs us that this opinion is erroneous. He ſays however, that although it does not deſtroy clover, yet it promotes not in any ſenſible degree the growth of it; and that he has uſed ſoot as a top-dreſſing for clover and ray-graſs in all proportions, from one hundred to ſix hundred buſhels on an acre, without perceiving the clover to be in the leaſt degree more luxuriant than in the places where no ſoot had been applied.

But the effects of this manure upon ray-graſs is amazing, and increaſes in proportion to the quantity. Hence in fields dreſſed with ſoot, the ray-graſs ſo far overtops the clover, that the latter is not ſeen, and the whole crop ſeems to be ray-graſs; although in fact there is as much clover as if it had not been manured at all.

Soot ſeems particularly favourable to the growth of graſs; for where a heap of it has lain ſo long on the ground as to deſtroy all the plants upon its ſurface, the firſt plant that appears afterwards is the common quich or couch-graſs: as the firſt plant that appears where ſtable-dung has lain is the common knot-graſs or hog-weed'.

Peat-Moss containing an acid nearly in proportion of one-fourth of its weight, its other valuable parts, oil, alkaline ſalts, and vegetable earth, are not only locked up, but the whole maſs is prevented from fermenting, by which proceſs alone it can be rendered uſeful.

To bring on the deſired fermentation, dry the peat-moſs well, break it into ſmall pieces, and lay it on the ground to the thickneſs of three or four inches. Let the whole of the dung from the ſtables be laid over it. The moiſture of the dung will ſink down, and not only correct the acidity, but ſaturate the peat-moſs completely with the valuable properties of the dung. Turn the dunghill over, and mix the dung and peat-moſs carefully together, throwing them up lightly, and a gentle fermentation will come on. After a few weeks turn it over again; adding one load of lime to five loads of moſs; the whole being well broken and accurately mixed. The addition of the lime will haſten the putrefaction of the moſs, diſſolve the oil contained in it, and give a due degree of activity to the whole.

Another way of effecting this is, to pour the urine of cattle, the moiſture of the dunghill, ſoap-leys, and offal of the houſe upon the peat-moſs; and afterwards to mix it with ſtable-dung and lime.

A third way of rendering peat-moſs uſeful as a manure, is to mix it with pot-aſh, kelp, lime or aſhes. In diſtant parts of the country, in the neighbourhood of bogs where peat-moſs abounds, and other manures are ſcarcely to be obtained, it may be highly important to know, that eighty or one hundred pounds weight of pot-aſh is ſufficient to ſaturate a quantity of peat-moſs that will manure an acre of land, and

[*] Farey in Young's Ann. 25. 67.

[*] Marſh. Norf. 1. 62.

[*] Anderſ. Eſſays, 1. 308.

that if it be well dried, a much ſmaller quantity of pot-aſh will ſuffice.

For this purpoſe diſſolve the pot-aſh in boiling water, half a pound to a gallon, and ſprinkle it over the peat-moſs, broken ſmall, and laid a foot thick, till it is ſaturated with the ley: then lay on a freſh ſtratum, treating it in the ſame manner. Leave the heap to itſelf ſome weeks, and then turn it, adding a quantity of the freſheſt and moſt active lime, worked well into the moſs with the ſpade: after ſome time it ſhould be again turned, and every part of it broken as ſmall as poſſible. In a month or ſix weeks, the whole will be ready for uſe.

Upon thin gravels or ſharp active ſoils, ſuch as chalk or limeſtone, this compoſt will be highly beneficial, not only as a manure, but alſo for thickening the ſtaple. *See Peat-aſhes.*

Decayed Vegetable Subſtances, are all uſeful as a manure. Some probably are little more than common earth or mould; but others have oily and other particles in them of conſiderable value. Mortimer reckons the rotten wood of hedges and coppices to be a great improver of the ſoil, and inſtances the earth where piles of faggots ſtand.] Miller remarks, that rotten wood, and ſaw-duſt when rotted, are a very good manure for ſtrong land, becauſe they looſen the earth and render it light. [Saw-duſt freſh from the pit, is not worth the carriage, although in a well rotted ſtate it becomes an excellent manure. All theſe ſubſtances may be added to ſtrong heating dunghills. As may alſo the graſs mown from lawns.

Leaves of trees may be collected at the fall and formed into a heating dunghill. They have been found to anſwer as a manure for potatoes.

The ſurface earth of woods, coppices and plantations, being formed chiefly of rotten ſticks and leaves, is very uſeful to the gardener for his flowers, mixed with land, loam and rotten dung.

CHARCOAL

Has been ſucceſsfully uſed as a manure. It is one of the ſubſtances which Mr. Arthur Young has employed in his experiments, and found to do good. See *Annals*, vol. 1. 151, &c.]

PLOUGHING IN GREEN CROPS.

Many ſorts of vegetables may be ſown, in order to be ploughed in when they are in full growth, to enrich the land. The ancients ploughed in Lupines for this purpoſe, and that practice is ſtill continued in Italy and the South of France; but they are too tender for our climate, and we have better plants for the purpoſe, as Peas, Beans, Buckwheat, Turneps, Vetches, Clover, Spurrey, and other moiſt and juicy plants, as Muſtard, Colefeed and other large-growing plants, cut before they form their ſeeds; when they are in full bloom, and abound moſt in ſap.

When we conſider at what ſmall expenſe of prime coſt, carriage, and other charges this manure is obtained; and how it completely ſmothers the weeds; it is wonderful that it has not more generally been adopted. It might no doubt be uſed on many occaſions, in place of a complete ſummer fallow, as a preparation for wheat: in which caſe the price of the ſeeds, which is almoſt the only expenſe, would be amply repaid by the ſaving in the article of labour.

Their value might be much improved, by laying on a certain quantity of lime, chalk or marl, according to the nature of the ſoil; which would tend greatly to haſten the fermentation, and bring the land ſooner into a proper ſtate for affording nouriſhment to the ſucceeding crop of wheat.

EARTH.

Maiden or untried earth, ſuch as is found ſix or ſeven inches deep under turf on commons, headlands, and by the ſides of roads in many places, when it is of a good quality, is of ineſtimable value as a manure for fruit-trees, raiſing ſhrubs and trees in nurſeries, all ſorts of crops in kitchen-gardens, and ornamental flowers, as well as corn and graſs. The nurſery-men near London ſend many miles for a loamy maiden earth, as abſolutely neceſſary for their purpoſe. Mr. Lawrence recommends it in preference to dung for both fruit and kitchen-garden, particularly for Aſparagus, laid a foot and half deep, without any dung whatſoever.

Mixed with dung or lime it makes excellent manure for corn or turneps. *See Compoſt.*

Fuller's earth, being of a very fat nature; though not much uſed for the improvement of land, on account of the profit it yields for cleanſing and ſcouring woollens, &c. is recommended as a great improver of ſome ſorts of land, by Sir Hugh Plat, Markham, Mortimer, and others.

Doubtleſs there are many ſorts of Earth that might be employed with ſucceſs beſides thoſe in common uſe, if they were examined by men ſkilled in their reſpective properties, and applied by thoſe who are verſed in their operations.

LIMESTONE.

In remote parts of the country, where limeſtone abounds, without fuel to burn it, if means can be found to break it ſmall at no great expenſe, it will be found uſeful as a manure. Attempts have been made in Scotland by Lord Kaimes to pulverize it. Where quarries of limeſtone or marble are worked, the duſt and chippings may be collected; but the only means of employing it on an extenſive ſcale is to pulverize it by a machine going by water or ſteam, upon a principle ſimilar to the large hammers uſed at iron mills. Chalk, other ſorts of ſtone, marl, crag and ſea ſhells, may be pounded in the ſame manner. Monſ. Duhamel found by accident that the powder of marble is a good manure for graſs.

The ill-burnt unſlakeable lime-ſtones, thrown out from the ſifted lime in building, upon part of a field in a mooriſh ſoil, the whole of which had been pared and burnt for turneps, and the other part manured for dung: the lime-ſtoned part had much the beſt produce; and afterwards when tilled for oats and ſown with clover, and even after that for ſeveral years, had always a manifeſt ſuperiority over the dunged part[a].

Limeſtone is calcareous earth indurated, with a ſmall quantity of quartz and argillaceous earth. Not only the common limeſtones, but Portland, Purbeck, &c. belong to this claſs. They all effervеſce with acids, fixed air entering largely into their compoſition: they will not give fire with ſteel: and contain a ſmall quantity of iron. They are all reducible to lime by the application of heat[b].

Limeſtone gravel is a marl mixed with large lumps of limeſtone, which when ſpread upon the ground, gradually fall into ſmaller pieces. If the pieces are large, and diſſolve ſlowly, the quantity applied ought to be great, and the effects will be ſlow and laſting; but if they are ſmall, it will operate more quickly, and laſt a ſhorter time. This is a conſiderable article of manure in Ireland, but is little known in England[c].

CHALK

In its native ſtate is uſeful as a manure upon the ſame principle as Limeſtone; but it is more eaſily pulverized, and lighter or more porous. Nearly the whole of it is calcareous earth; whereas no marl contains more than a fourth part of that ſubſtance.

Chalk is in high eſteem in the ſouthern counties of England, where it abounds. Its beſt effects are upon deep ſoils, which contain no calcareous earth. It is obſerved to have very little effect upon lands where the ſubſtratum is chalk; and if the ſoil be thin, it does miſchief. When uſed upon light ſoils, it is made into compoſt with earth and dung. When this is well mixed and duly proportioned, it produces valuable crops, and its influence continues many years.

The common method of uſing this compoſt, is either to lay it upon fallows for wheat, and mix it intimately with the ſoil, or upon graſs as a top-dreſſing: in both caſes it anſwers well; in the latter it deſtroys moſs rulhes and all coarſe aquatic plants that grow in four or wet lands; in the former it opens and pulverizes the ſoil, and never fails to produce good crops.

Chalk ſhould be broken as ſmall as poſſible. It ſhould be dug near the end of autumn, and laid

[a] Gutler in Y. Mag. 4. 492.
[b] Wilkinſon in Y. Mag. 21. 102.
[c] Abbott. Hiſtor. vol. 1.

on

on immediately; at that ſeaſon the air is generally moiſt, the moiſture will be abſorbed by the chalk, this will occaſion it to ſwell and break in pieces, and if froſt come on, it will accelerate the buſineſs: but when it is dug in ſummer, it loſes its moiſture, and acquires a hardneſs, which in a great meaſure prevents it from being of any uſe.

Chalk ſhould in no caſe be ploughed in till its parts are properly ſeparated, and then it ſhould be completely harrowed in, and well mixed with the ſoil.

If the ſoil be thin and light, a certain proportion of dung will be uſeful; but if it be heavy, the dung will only leſſen the operation of the chalk. It is generally thought that lands which have been completely chalked, will not bear a repetition of it. A compoſt of it however may be uſed to great advantage. In the ſouthern counties a field has been chalked and dreſſed with chalk and dung mixed in pieces alternately, and the former has produced a very bad crop, and the latter a very good one.

Chalk beyond a certain quantity will not only ceaſe to operate as a manure, but even prove hurtful. It ought therefore be uſed with caution, and due pains taken not only to aſcertain the ſtrength of the chalk, but the quality of the ſoil upon which it is laid.

In ſome parts of Eſſex they lay from five to eight waggon loads of chalk on an acre, either upon a clover ley while feeding, or on a ſummer fallow: a very thin dreſſing of it is ſeen immediately to an inch, like rotten dung, and laſts twenty years, fifteen in good heart. The ſoil is loam; they have little clay and no ſand: on gravels the effect is but ſlight.

They bring the chalk from Malden, whither it is brought by ſea from Kent, and a waggon load coſts 10s. at the quay. It is rather hard; the ſharpeſt froſts leave many lumps unbroken; theſe they break with pickaxes. The effervescence with vinegar is pretty conſiderable; but in water it ſcarcely falls at all.

It is a general opinion in that country, that land which has been once chalked will not take it again; they acknowledge however that mixed with earth and dung it is even then excellent. They obſerve, that laying a ſlight dreſſing of chalk and earth or dung on a field never chalked, will take ſo much effect, that the ſame field will not anſwer to chalk completely. They obſerve alſo, that the chalk preſently gives the land a red colour. They are of opinion that chalk is a great enemy to good graſs; and affirm that a field which before chalking will run of itſelf to a fine head of white clover, no longer does it after chalking.

There is no ſaying any thing againſt experience: only we ſhould not draw general concluſions from partial experiments. Much of the effect of manures depends upon the ſoil on which they are laid. About Enfield the ſame chalk does wonders, which at North Mims has very little effect: the one is a rich loam, the other a poor gravel [a].

Near Sandwich in Kent chalk has been found in a very high degree to improve a ſandy ſoil, giving it tenacity, and totally exterminating that pernicious weed the Corn Marigold, provincially called Yellow bottle or buddle, or Golds, ſo abundant in ſandy ſoils. They lay on forty loads of forty buſhels each to an acre. Upon paſture land it does nothing [b].

In Hertfordſhire it is thought that chalk makes the land plough much better, and renders all manures much more effectual. If a field be divided in parts, one chalked, a ſecond chalked and manured with dung or ſoot, aſhes, &c., and a third dunged or aſhed without chalk; although chalk alone has no effect, yet the other manure on the chalked part, will have a much greater effect than on the part where no chalk is laid [c].

The action of chalk on the ſoil is either chemical or mechanical. It acts chemically as an abſorbent, contributing to preſerve dry thoſe lands which are poachy and wet; and by its attraction for acids, it may haſten the putrefaction of vegetables. It acts mechanically, by entering into the compoſition, and totally altering the nature of clay, converting it by proper pulverization into a ſpecies of marl: by inſinuating itſelf between the particles of clay, it deſtroys their adheſion; thus preventing it from becoming too hard in ſummer, and too wet in winter [d].

LIME

Is calcareous earth deprived of its fixed air and water, but which has acquired in calcination a conſiderable proportion of fire. Quick lime, like ſalts and earths, perhaps is not itſelf nutritive, but like alkaline ſalt, ſtimulates the vegetable, and thereby accelerates its growth, applied in due quantity and at a certain period of vegetation. If it be applied in larger quantity, it kills animals in the ſoil, and alſo ſmall vegetables; and from the deſtroyed and decayed animals and vegetables a ſoil is rendered fertile, becauſe impregnated with mucilage. The ſuperabundant lime does not prove hurtful, becauſe it becomes mild calcareous earth, by attracting carbonic acid from the atmoſphere. A moſt ſatisfactory example of the effect of lime is to be found in Derbyſhire, about Buxton, &c. where by throwing lime upon the heath, that ſhrub has been deſtroyed, and excellent graſſes, particularly white clover, have ſprung up in its room [e].

It is a common notion that lime enriches land, by ſupplying a ſalt fit for the nouriſhment of plants; but it contains no ſalt. By the fermentation it brings on, the earth is opened and divided, and by its abſorbent and alkaline quality, it unites the oily and watery parts of the ſoil. It alſo readily forms the acid which it collects from the air into a neutral ſalt, of great uſe in vegetation. Viewing lime in this light, it probably may tend to rob the ſoil of its oily particles, and in time to render it barren, unleſs it be ſupported with rotten dung, or other manures of an oily nature. Light ſandy lands containing only a ſmall portion of oil, ſhould not be overdone with lime, unleſs we can aſſiſt them liberally with animal manures. Its great excellence on a ſandy ſoil, is its mechanically binding the looſe particles, and preventing the liquid parts of the manure from eſcaping out of the reach of the crop. On clay, by means of the gentle fermentation which lime produces, the ſtubborn ſoil is opened; the manure readily comes into contact with every part of it, and the fibres of the plants have full liberty to ſpread. It is often ſaid that lime anſwers better upon ſand than clay; but let the farmer treble the quantity, and he will be convinced that lime is better for clay than ſand. Clay well limed becomes a marl, falling in water and fermenting with acids: the air, rain and dews are freely admitted, and the ſoil retains the nouriſhment of each. In conſequence of a fermentation raiſed in the ſoil, the fixed air is ſet at liberty, which in a wonderful manner promotes vegetation. It is the nature of lime to attract oils and diſſolve vegetable bodies. Upon theſe principles we may account for the wonderful effects of lime in the improvement of black moor land, which conſiſts of diſſolved and half diſſolved vegetable ſubſtances, and is full of oil. Lime aſſimilates the one, and diſſolves the other [f].

Reſpecting the proper quantity of lime, it may be obſerved in general, that the greateſt ſhould be uſed upon the deepeſt and richeſt ſoils, and the leaſt upon thoſe that are thin and light. Upon ſtrong clays and deep loams there is a ſubſtantial body for the lime to operate upon, containing abundance of rich ſubſtances, and conſequently a conſiderable quantity will be required to pervade and give due activity to the whole; but as the ſoil is lighter, the quantity muſt be leſs, and the after-management with regard to crops, extremely cautious. In liming a ſingle field, an attention to the quantity will often be found neceſſary; the ſoil of the higher parts being for the moſt part more light and free, and that of the lower more deep and compact, where the ground is unequal. On ſome ſoils, particularly where the bottom is chalk, limeſtone or marl, lime will be pernicious, eſpecially if the ſoil be thin.

Application of Lime.

First upon Fallows. It is found to produce the beſt effects in this caſe when laid on early in the ſeaſon, and well incorporated with the ſoil.

Secondly for Turneps. By the aſſiſtance of lime whole diſtricts, formerly uſeleſs, have been made to produce not only good crops of turneps, but alſo valuable crops of corn and broad clover. Its greateſt value however ſeems to be upon light ſoils for theſe crops, inſomuch that where lime is the principal manure, they ſeldom ſow turneps, clovers, peas or beans, except upon lands that have been previouſly limed. Inſtances of this are often met with on the uplands, where if any of the broad-leaved crops are ſown, where a part has been limed, and a part not, the parts where the lime has been laid will produce a valuable return, while that which has been dunged only will hardly repay the expenſe of ſeed and labour.

Farmers differ in their methods of uſing lime upon turnep-lands. Some lay it on only before the laſt ploughing, and plough it in without harrowing: they alſo lay it in heaps, hot from the kiln, without being ſlaked. But the ſooner it is laid upon the land, and the more ploughings and harrowings it receives before the ſeed is ſown, the better it will be incorporated with the ſoil, and the more certain and valuable will be its effects.

Thirdly, upon Clover-ley for Oats. This is perhaps the worſt way in which lime can be uſed. It is generally laid on in the autumn, and ploughed down in the ſpring, and the returns are inadequate to the expenſe.

Fourthly, as a top-dreſſing in ſpring, upon graſs, or wheat and other grain. Upon the latter it is dangerous, unleſs the lime be made into a compoſt with dung or earth: in this form it will not only be ſafe but profitable. Upon the former it is no better, except upon coarſe meadows, abounding with ruſhes and other trumpery, which it deſtroys.

Upon light ſoils, if ſeveral white crops be taken in ſucceſſion after liming, the land will be worn out. A white and a green crop ſhould be taken alternately. Upon clay lands a ſummer fallow is ſometimes indiſpenſible, in that caſe the lime ſhould be laid on in July or auguſt, and completely harrowed in before ploughing; two or three ploughings at leaſt are required to incorporate it well with the ſoil, and a ſuitable harrowing with each.

Conſidering lime as a ſubſtance operating upon the living ſubſtances in the ſoil, as well as mechanically upon the ſoil itſelf, we perceive the neceſſity of applying a ſufficient quantity at once, in order to produce theſe effects: for if the quantity employed be ſmall, and the ſoil deep, its effects will be ſcarcely perceived. Many farmers imagine that lime will not anſwer upon their lands, becauſe they have laid it on in ſmall quantities, whereas in all probability they would have found a larger doſe highly beneficial. On clay four or five hundred buſhels are laid on for wheat, but it can ſcarcely be expected to anſwer the expenſe. On moſs, bogs, moor, &c. to be reclaimed from a ſtate of nature, the more is laid on, the better it is.

The beneficial effect of lime on ſandy land may be explained from its binding quality. But when ſuch lands are firſt broke up from their ſtate of heath, the vegetable matter is acted upon, and reduced to manure by the corroſive power of the lime. On ſuch lands, the firſt crops of rie has more than paid the expenſes. By attracting water lime lays land dry.

By inſinuating itſelf between the particles of clay, it deſtroys their adheſion, breaks the ſtiffneſs of the ſoil, and gives readier acceſs to the operation of manures, and to the extenſion of the growing roots of plants.

By attracting fixed air, water and acids, and by its corroſive properties, it deſtroys the texture of bodies, and reduces vegetable matter to a ſtate of manure. It unites ſtrongly with oils, and renders them miſcible with water.

By being deſtructive to inſects and vermin, it may contribute to preſerve the ſpringing corn from their ravages.

If the lime is to lie in a heap for any length of time, it ſhould be covered with earth, to preſerve it from the air and rain.

It is obſerved that the benefit of lime is not apparent in a dry ſummer, and that it does not act as a manure till it has been thoroughly ſlaked in the ſoil, by continued rains.

In Eſſex an excellent practice prevails, of forming a compoſt of lime, turf and ditch earth, at the gate of every field, ready to be applied as a manure when wanted.

Twenty buſhels of lime mixed with forty buſhels of ſand, form an excellent top-dreſſing for an acre of wheat, if laid on early in the ſpring.

Lime is apt to ſubſide beyond the depth of the common furrow: deep-ploughing in this caſe is the only remedy applicable[1].

In ſome midland counties a fallow is ſeldom made without being dreſſed with lime, under an idea that it mellows the ſoil, and makes it work well, while in ſtillage, and ſweetens or improves the quality of the herbage, when laid down to graſs. For this purpoſe it is fetched eighteen or twenty miles.

Two ſorts of lime are in uſe. The Breedon lime, burnt from a very hard ſtone, and of ſingular ſtrength as a manure; and the common lime burnt from common ſtones, and called Ticknall or Walſal lime.

The load heaps are generally watered as they are thrown down from the waggon; and always turned over to complete the ſlalling more effectually.

If a quantity of lime be fetched in autumn or early in winter, to be uſed in the ſpring, when team-labour is more valuable, it is thrown up into a regular roof-like heap or mound, and thatched as a ſtack, a ſmall trench being cut round the ſkirts to catch, with an outlet to convey away, rain water. Thus the heap is prevented from running to a mortar-like conſiſtence by the ſnows and rains of winter, and thereby rendered uſeleſs as manure.

A turnep fallow was manured with Breedon lime in general five quarters to an acre; part had double that quantity, and part had none. The turnep crop received no obvious advantage, but its effects on the barley were evident. The part not limed was the worſt crop, nearly in the proportion of four to three. But the part limed with ten quarters to an acre was the beſt crop. Whence the common notion that more than five quarters of Breedon lime to an acre is ruinous to crops, ſeems to be ill founded[2].

Lime is in good repute, though not in general uſe in Norfolk, as a manure; different opinions being entertained reſpecting the value of it. This difference of opinion will ever remain, while general concluſions are drawn from particular incidents. It is uſed by many judicious farmers even after marl, with ſucceſs. Upon hot burning ſoils it is generally found of the greateſt efficacy, and is perhaps the moſt effectual cure of ſcabs or burning patches of land that has yet been diſcovered; from theſe and other circumſtances lime is here conſidered as a cold manure.

The general method of applying lime is to let it fall in large heaps, and to ſpread it out of carts upon fallowed ground either for wheat or barley. The quantity ſet on is about three chaldrons an acre: the price 9s. or 10s. a chaldron. From experiments made on turneps, barley and wheat, it appears that lime does not act as a manure until it has been thoroughly ſlaked in the ſoil; and it ſeems as if the rains of ſummer were neceſſary to promote its operation[3].

In ſome parts of Yorkſhire Lime is uſed invariably on every ſpecies of ſoil, and in moſt caſes with great ſucceſs.

On the higher drier lands its utility is evident. At Malton, it is laid on the calcareous quarry ſoil with ſucceſs. Its uſe to the looſe ſandy ſoils is fully eſtabliſhed.

The prevailing crop is wheat on fallow. It is alſo pretty generally ſet on for rape, turneps or other crop.

[1] Wilkinſon in Y. Ann. 21. 105.
[2] Marſhall's Midl. 1. 198, and 2. 229.
[3] Marſh. Norf. 1. 30, 161. and 2. 55.

after ſod-burning, and ſpread among the aſhes. It is alſo ſometimes ſet on for barley. But its effect to the firſt crop, except of wheat or rape, is ſeldom perceptible.

The benefit of lime to graſs is a matter of diſpute; it is even thought by ſome to be detrimental. It ſeems however to be a generally received idea, that lime laid on graſs is not thrown away; for whenever the land is turned up again, its benefit to corn will have full effect.

Their methods of liming are various. The worſt is, laying it in large heaps, and ſuffering it to run to a jelly before it is ſpread.

Next to this, is ſetting it about the land in ſmall hillocks: for although they are ſpread before they approach to a ſtate of mortar, yet this method is injudicious. Lime falling in the open air, breaks into ſmall cubical maſſes, which being once buried in the ſoil, remain in it for ages, without being mixed intimately with it. Lime ought therefore to be ſpread in a ſtate of perfect powder.

It is therefore the practice of judicious huſbandmen to ſet lime upon the land in load-heaps, and ſpread it over the ſoil out of carts, as ſoon as it is ſufficiently fallen. Or the load-heaps are turned over, not ſo much to finiſh the falling, as to gain an opportunity of burying the granulous ſurface of the heaps; by which means the fragments are at leaſt leſſened, if not reduced to powder.

In the Moorlands the heaps are interlayed and covered up with moiſt turf or peat-mould, which bringing on a rapid fall, the whole is ſet on fire, and the ſurface kept free from granules by a covering of dry aſhes.

The heaps, therefore, whether great or ſmall, ſhould be covered up with ſoil, either of the field they are ſet in, or that of lanes or ditches carried to them for the purpoſe; and if a ſpeedy fall be required, throw water over this covering.

If lime be uſed on fallow for wheat, it is generally ſpread in July, harrowed in as faſt as it is ſpread, and ploughed under with a ſhallow furrow as ſoon as convenient. The uſual quantity is three or four chaldrons to an acre[1].

Mr. Young, from various minutes made in his Eaſtern tour, concludes, that lime agrees with almoſt all ſoils: that it fails however on a thin loam on lime-ſtone; that it ſeems inefficacious on old paſture; that it has a ſtrong effect in killing weeds; and that the greateſt effect is on heath and moor-lands; where, as in the Peak of Derbyſhire, it converts waſte ſoils into fine paſtures, without tillage; but the ſort is a ſtrong ſtone lime, burning ſoft and ſoapy, and the quantity laid on is very great, riſing to three hundred and ſixty or even one thouſand buſhels; but the common quantity is about four hundred buſhels. There is great reaſon to attribute much of the benefit to quantity: in waſtes eſpecially, too much can hardly be laid on, becauſe diſſolving the roots of heath, and other ſpontaneous growth requires a powerful agent. Of their ſtrong lime three hundred and ſixty buſhels are probably equal to five hundred or ſix hundred buſhels of chalk lime. What then are five or ſix quarters, which is no uncommon quantity, laid upon an acre.

The Derbyſhire mode of uſing lime in improving their heaths or moors, is firſt to pare the ground in the beginning of march about an inch and half thick, to turn it about in dry weather, when dry to gather it into heaps, and burn it into aſhes, to ſpread them even over the ground, to ſet their lime, to ſpread it and harrow it all together, to plough the ground very thin, and to ſow it with turneps or rape: then the ſpring following to ſow with oats or barley, and good graſs ſeeds; another good dreſſing with lime after the firſt crop of ſeeds is got; and then it may lay for paſture. Spreading the lime in a ſlaked ſtate, is by far the beſt method. The ſummer months are preferred, becauſe fewer coals are neceſſary for burning; in other reſpects the winter months are juſt as good for laying the lime upon the ground.

[1] *Marſh. Yorkſh.* 1. 347.

Dr. Anderſon is very copious upon the ſubject of Lime, both as a cement and a manure, in his Eſſays relating to Agriculture. It is remarkable that Mr. Miller has not mentioned Lime as an article of Manure; though Mortimer and other old authors on huſbandry have written ſenſibly about it.

MARL.

Has been long celebrated as a manure. Our writers on huſbandry of the laſt century treat largely on it. Gervaſe Markham has a treatiſe expreſsly on the ſubject, entitled, The Inrichment of the Weald of Kent; in which he ſays, that Marling was the practice of our forefathers many centuries back, even in the time of Edward II. He enumerates four ſorts, "grey, blew, "yellow and red; all which be profitable, if they be "earthy and fat, or ſlippery as ſope: and moſt times "little worth, if they be mixed with ſand, gravel or "ſtone."

Walter Bligh has ſhown the nature and uſe of Marl, with experiments of his own upon it, in his Engliſh Improver Improved, 1653.

Mortimer alſo has a long and good chapter on the ſubject, in which he mentions that there are five ſorts of Marl in Cheſhire.

Few ſubſtances appear under a greater diverſity of forms than this, and writers on Agriculture enumerate the ſeveral varieties as diſtinct manures; they may all however be reduced to two ſorts, Earth or Stone Marls, and Shell Marls.

The firſt, when they are ſoft and of an uniform texture are called Clay Marls; when firm and hard, Stone Marls; when they aſſume a thin foliaceous appearance, Slate Marls. They all agree in this, that if they be expoſed for a ſufficient time to the action of the air, they crumble into ſmaller parts, and fertilize the earth to which they are properly applied. Dr. Ainſlie has ſhown that they all contain a conſiderable proportion of clay, united with calcareous matter, not differing in any reſpect from that in limeſtone.

When marl is expoſed to the air, the clay in its compoſition abſorbs the moiſture of the air and rains, ſwells, become ſoft, and gradually crumbles to pieces.

When ſand is mixed with the clay, it becomes a ſtone, more or leſs firm according to the quantity of ſand, or other circumſtances. But where there is any clay in the compoſition, it will be gradually ſoftened by water: and it is owing to this circumſtance alone, that ſtone-marls fall to pieces in time, when expoſed to the air.

But if marl be expoſed to the action of a moderate fire, the clay becomes hard, and no longer capable of abſorbing water; ſo that the marl, if not of a very pure ſort, or ſuch as contains only a very ſmall proportion of clay mixed with the ſand, will become firmer after burning, and be in this ſtate with more difficulty reduced to powder. Marl therefore is fit to act as a manure without any other preparation than digging it from the pit, and ſpreading it upon the ground; whereas lime-ſtone requires to be reduced to a powder by burning or otherwiſe, before it can be uſed in this way. As lime-ſtone is at once reduced into much ſmaller parts by calcination than marl can be brought to at firſt, a much ſmaller proportion of lime may be equally ſpread over a piece of ground than of marl, and will produce, in equal quantities a much more ſenſible effect. Hence a much larger quantity of marl than of lime is applied at one dreſſing: from one to two hundred cart-loads being a common dreſſing for an acre, that is from three thouſand to ſix thouſand buſhels, whereas three or four hundred buſhels is a very great dreſſing of lime upon an acre.

In ſo large a quantity it is reaſonable to think, that the effects of the marl will be longer felt than thoſe of the lime: for the marl being gradually broken into ſmaller pieces every year, will ſucceſſively mix with the ſoil, and produce an effect ſimilar to an annual dreſſing with lime.

It may likewiſe be expected that a full dreſſing of marl, will produce more improvement upon light ſpongy grounds, than an ordinary dreſſing of lime; becauſe, independent of the calcareous matter, the large proportion of clay applied in this manner, may

produce some alteration on the quality of the soil. This alteration however will be different, according to the nature of the extraneous matter contained in the marl.

But all marls containing clay, it is natural to think that clay-lands will not be benefited by this circumstance; the calcareous matter alone in these cases being an useful addition to such soils. Hence light land will be in general more highly benefited than clay-land; according to the old rhyming saying—

"He that marls Sand, may buy land,
"He that marls Moss, shall suffer no loss,
"But he that marls Clay, flings all away."

Clay however is as much benefited by the calcareous matter in marl as sand is: so that a rich marl may be nearly equally beneficial in both cases.

Some clays however, free from any mixture of sand, assume the appearance of marl, and are so called, although they contain little or no calcareous matter. These may perhaps be a useful addition to light soils, but cannot be of any service to clays.

Whether lime or marl should be preferred as a manure, must depend upon the situation of the place, the purity of either respectively, the price, expense of carriage, &c. If marl be rich, and near at hand, it is in general more advantageous to him who has a prospect of enjoying his farm for a long time than lime. But when it must be brought from a distance, lime will be the cheaper manure [a].

Shell Marl is a whitish powder formed by the gradual decomposition of shells. It is therefore a calcareous substance, and is mixed with mud or parts of the mossy stratum, under which it is generally found, fragments of rotten wood, &c. From this extraneous admixture it is more or less pure. It is usually a light spongy substance, very slightly coherent. Since it admits of being spread as equally as lime, it may in general be carried with profit nearly as far, except that shell-lime of the best sort wants a great proportion of its moisture, air, &c. which greatly diminishes its weight.

Shell-lime is however a great treasure wherever it is discovered; and where fuel is scarce and dear, is of much greater value than even the best limestone, since it produces the same effect upon the soil with lime, can be as equally spread, and can be obtained at a much smaller expense [b].

Dr. Hunter has an elaborate essay on the nature and properties of Marl. From his analysis and experiments it appears that marl consists of clay, or a mixture of clay and sand, and of a real calcareous earth, differing in no respect from that of limestone and the shells of animals. According to him, the essence of marl consists in this calcareous earth. All bodies however which have calcareous earth are not marl. To entitle them to this name, they must fall into powder upon being exposed to the air. Hence the purity of marls will be in proportion to the quantity of calcareous earth in their composition.

The different proportions of the constituent parts of marl in the several varieties of it, making a choice of marls for particular soils a matter of consequence; it is desirable to know the process for discovering this proportion.

Having dried and powdered the marl to be examined, pour upon any given weight of it a small quantity of water. To this mixture well shaken add a little acid of sea salt, or any other mineral acid, except the vitriolic; and when the effervescence is over add a little more. Repeat this addition at proper intervals, till no more effervescence entues. Then put the whole, with an equal or greater proportion of water, into a filter of gray paper, the weight of which is known. When all the fluid parts have passed through, fill up the filter again and again with warm water. Thus the dissolved particles of calcareous earth, adhering to the residue, or entangled in the pores of the paper, will be washed away, and nothing but what is really insoluble will remain in the filter. This residue, with the filtre must be dried and then weighed. The difference between its weight, and the original weight of the filtre, gives the weight of insoluble parts. This being known, the proportion of calcareous earth in the same marl is evident. The proportions of clay and sand in it are discovered by subjecting the residue to a proper elutriation or washing, which is thus performed.

Having weighed the dry residue, mix and shake it well with a sufficient quantity of water. After allowing a little time for the subsiding of the grosser parts, let the water with the finest particles of clay suspended in it, be gently poured off. Add more water to the remainder, and after sufficient mixture and subsidence, pour that off likewise. In the same manner repeat the operation again and again till the water comes off perfectly pure. The substance which then remains is sand, mixed perhaps with some flakes of talc; and whatever this substance wants of the weight of the residue, is the weight of pure clay, carried away by the water in the washing.

The effervescence ensuing upon the application of acids to marl, although it shows the existence of calcareous earth, yet is no indication of the quantity of it: for the effervescence varies, according to the strength of the acid employed; but still more according to the penetrability and other more latent qualities of calcareous bodies.

The calcareous earth of marl is equally calcinable to quick-lime, whether it is exposed to the action of fire before or after its separation from the other earths which it contains.

Marl indeed has a very intimate affinity to limestone. A gentle gradation from one to the other may be easily traced out; and it will be difficult to establish the precise limits of either. Both are found in continued strata; both dissolve in part with considerable effervescence in acids, and both yield by calcination a quick-lime. There are however two remarkable differences: marl, by being exposed to air, falls into powder; limestone retains its original stability. On the contrary, limestone, after undergoing the action of fire, is reduced to powder by the application of water; marl suffers no change [c].

In Norfolk it is well known, that through the fertilizing quality of marl judiciously applied, lands which were a scanty maintenance for sheep and rabbets, have been rendered capable of fattening bullocks, and bearing great crops of corn.

The principal marls used in this county are the Chalk-Marl, such as that of Thorp-Market in the hundred of North Erpingham: and the Clay-Marl, such as that of *Hemby*, in the hundred of East Flegg. The soft Chalk also of Thorp next Norwich, commonly called Norwich Marl, and the hard Chalk of Swaffham, are used as marls.

1. The Chalk-Marls or White Marls are not found in strata, but in nodules or distinct masses, irregular, of different forms and sizes, having the appearance of a dirty, rough, friable chalk. One hundred grains contain eighty-five of chalk, ten of sand, and five of clay.

2. Clay-Marl is found in extensive beds of considerable depth. Its colour, when dry, somewhat lighter than fuller's-earth. Its contexture that of gritty fuller's-earth, interspersed with granules of white chalk. One hundred grains contain fifty of clay, forty-three of impure chalk, and seven of sand. They both fall in water, without dissolving in it; they both break readily in the open air, and mix freely with the soil: in the fire, the first burns to lime, the second to brick. In acid of sea-salt, part of the first is dissolved, but the greater part is indissoluble; of the second almost the whole is dissolved.

3. The soft Chalk, forming a bank of the river Yare, is a pure calcareous earth, ninety-eight grains out of a hundred being soluble in acid of sea-salt. The celebrated chalk of Betchworth-hill, which is fetched twelve or fourteen miles as a manure by the Sussex farmers has a residue of more than one-tenth of its weight, whereas this affords only one-fiftieth.

[a] Anderson, Essays i. 415. [b] Ibid. i. 426. [c] Essay 16.

4. The

4. The hard chalk of Swaffham is nearly a pure calcareous earth. They neither fall nor diſſolve in water, and burn to lime in the fire. They are not marls, but are uſed for manure as ſuch.

The name of Marl is in ſome places applied to all white unctuous earths, whether they contain any calcareous matter or not. Clay-Marls are commonly called Clays; and the operation of marling with theſe is called Claying. Hence one ſeeing the good effect of Clay-marl, ſuppoſes that all clays are fertile; and uſing a bed of ſtrong brick-earth for manure, which he finds of no ſervice, concludes that all clay-marls are unprofitable. Another ſeeing this, fetches marl from a great diſtance, while he has perhaps, on his own land, an earth of a quality equally good with that which he is at the expenſe of fetching.

In Norfolk the quantity of marl ſet on an acre, where it is fetched from a great diſtance, is ten or twelve loads; but where it is on the farm, twenty to thirty loads, or tons, and ſometimes forty, are allowed to an acre.

When it is known or ſuppoſed, that land, from having been recently marled, or from ſome other cauſe, is not improveable by marl alone, it is made into a compoſt with dung; and this has been found to anſwer.

They judge that land requires marling, by its producing Buddle or Corn-Marigold, and Smart-weed (Polygonum perſylvanicum). Marl certainly extirpates theſe weeds, and checks quicks, quich or couch (Triticum repens).

Marl is ſet on for turneps, for barley, and frequently upon the ſecond year's lay for wheat.

The expenſe of marling muſt vary with the quantity, diſtance and ſtate of the pit. Suppoſing twenty-five loads an acre to be ſet on, the diſtance from a quarter to half a mile, the expenſe of caſting 3d. a load, and that a team draws out and ſets on the twenty-five loads in two days, the whole expenſe of marling an acre will be 40s.*

Mr. Young concludes from the minutes made in his Eaſtern tour, that marl agrees with both ſtiff and light ſoils. The great ſucceſs attending it in Norfolk ſhows how well it anſwers on ſands and light ſandy loams: but numerous experiments on heavy and light land, prove it beſt on the former. It has a ſtrong effect in mellowing the land, and making it work better; by which we are to underſtand that it renders wet lands drier, and ſtiff ones more friable; ſo that both may be ploughed earlier in the ſpring, and one earth have the effect in pulverization of ſeveral. It alſo appears to clean the ſoil of weeds; though whence this ariſes is difficult to conjecture, ſince it is a weak ſolvent in compariſon with lime.

From experience of marl on various poor ſands in Norfolk, it appears not merely to improve by giving them tenacity, but to be a great fertilizer: it is difficult to comprehend how mere adheſion of parts, naturally poor, can produce ſuch great crops; but the quantity of rich ſoil carried on is ſo great, that it creates in a manner a new ſtaple. The duration of the effect indeed ſeems to depend much on quantity. On ſand in Norfolk it laſts twice as long as on loam in Surry, &c. The ſame quantity will laſt longer on a ſtiff ſoil than on a looſe one; as a dreſſing of yard dung laſts longeſt on a ſtiff true tile clay.

The expenſe of marl at ſome places is very great. About Yarmouth, in Norfolk it is 7s. 4d. a cart-load. About Colcheſter they have it from Kent, it coſts them from 7s. to 9s. a waggon-load, they carry it ten miles, and lay ſeven waggon-loads on an acre.

Marl has been much uſed in Staffordſhire for ages back. In many places, they ſay, the land has been over-marled and is rendered harſh; this is reſtored by fallowing and liming. It is in general only in loamy ſoils that a true marl is found; in mixed gravelly ſoils they have a friable brick clay, which is uſed on ſuch ſoils with good effect: the quantity laid on is generally one hundred and twenty-eight cubic yards on an acre, which adds nearly an inch to the ſtaple of the ſoil; the expenſe is about 25s. an acre, beſides carting out, which is worth 30s. an acre more. It is thought to be much more adapted to tillage than paſture, and its good effects on corn-lands are long viſible: in thin light lands it endures for ever, as it not only conſolidates the ſoil, but gives it ſtaple*.

Marl is the foundation of improvements in agriculture in Lancaſhire and Cheſhire. They have ſeveral varieties of it, valuable in proportion to the calcareous matter which they contain, or the nature of the ſoil to which they are to be applied. To ſtiff clay-lands the blue or reddiſh ſtare-marl, or ſhell-marl, containing much calcareous earth with ſome ſand, are more beneficial, but to light ſands ſtrong clay-marl is more genial.

Barren ſands and poor heaths have been rendered productive by marl, but at a great expenſe: indeed there is reaſon to believe that the greateſt part of the ſouthern diſtrict of Lancaſhire has been reclaimed by it.

The general cuſtom is to lay upon the great Cheſhire acre of eight yards to the rood, from three to ſeven roods of ſixty-four ſquare yards each. From four to five roods may be conſidered as the average quantity; but it ought to be in proportion to the quality of the ſoil and of the marl. A Cheſhire acre contains two acres, eighteen perches and a half ſtatute meaſure. They lay it upon graſs-land, which is intended to be broken up the enſuing ſpring. Sometimes a coat of marl is ſpread upon the green-ſward, and left unploughed many years; in this caſe the graſs ſometimes receives conſiderable detriment, the marl ſinking down in a body without incorporating with the ſoil: though when marl has lain ſeveral years in this ſtate, the ſubſequent crops of corn have been enormous.

The general rule is to begin marling in May or June, in ſhort when ſpring ſeedings are over, continuing as opportunity ſerves during the ſummer months: it is not however unuſual to take a crop of hay firſt. In either inſtance, the effects of the marl become ſpeedily viſible by the rich verdure of the graſs. Marl is ſpread immediately, but left in a rough lumpy form, that it may be expoſed as much as poſſible to the weather: if it contains much clay, it will remain many weeks or months; but in general the rains of autumn and the froſts of winter reduce it to an unctuous but friable material, the diſperſion of which is eaſily effected with cloſing beetles, ſpades or harrows, a week or a fortnight before ploughing. By this long expoſure it is more than probable that the marl may acquire by attraction its moſt nutritive qualities. The turf, when ploughed under, anſwers the purpoſe of a rich vegetable manure.

Many of the Lancaſhire farmers ruin the land thus manured, by taking repeated crops of oats, with the interval of one ſummer fallow for wheat, by way of cleanſing the land; after which barley and oats again, ſo long as the land will produce any thing; and then laid down again with weeds and couch-graſs. Whereas their land would be kept in heart, if they would take one crop of oats, plough the ſtubble immediately to expoſe the marl to the influence of the froſt, fallow with manure for turneps; then barley, clover, wheat, turneps fed off with ſheep, and barley again with well-dreſſed hay-ſeeds and white clover and trefoil for a perennial hay, or at leaſt for ſome years. The land thus huſbanded will produce in a moſt exuberant degree, and at the ſame time is rendered perfectly clean from all weeds, without being in the leaſt harraſſed. Even poor ſandy ſoils are thus rendered capable of producing the beſt herbage, and under proper management may be depended upon in all ſeaſons.

Leiceſterſhire farmers object to marling, becauſe it is unfavourable to graſs. In Lancaſhire they can have no good graſs without it. This difference ariſes from the application. If marl, according to the Leiceſterſhire ſyſtem, be put upon a turneep fallow, and immediately ploughed under in its crude ſtate, no wonder it produces no graſs and little corn. In Lancaſhire it is expoſed at leaſt five months, and always to a winter's froſt; hence ariſes its bench to graſs.

* Marſh. Norfolk.

* Pitt, Survey of Staff. 127.

The original marlers in Norfolk, and their ſucceſſors grew rich: at preſent we are told, that the land will not bear marling twice; an idea utterly diſcountenanced by the Lancaſhire practice. And from this idea it ariſes that Norfolk is ſaid to require another ſyſtem of cropping; that turneps and clover come round too often, &c. What are we to infer from this? Probably that the ſame material, properly applied, that cauſed the original improvement will reſtore the land to its former fertility: at any rate the experiment is worth trying.

In Lancaſhire they think it a much better practice to have the marlings repeated, with a gentle covering, than to lay it ſtrong thick coat to laſt many years.

Marl does not produce its full effects upon the ſoil, till it is incorporated with it by ſeveral ploughings, and ſome or other oily manure mixed with it.

One hundred grains of Lancaſhire marl contains from forty, and a half to thirty-two ſeven-tenths of ſtony land, from thirty-nine to forty-ſeven three-tenths of clay and ſilicous earth, and from nineteen and a half to twenty-two calcareous earth[7].

Mr. Kirby, near Ipſwich, manured an old ſheep-walk with clay-marl, eighty loads an acre of thirty-ſix to forty buſhels each. It is left a year on the walk before breaking up, and then ploughed for peas.

Mr. Coke, of Holkam in Norfolk, who has marled many hundred acres, always ſpreads the marl on the new lay, that is on the ſeeds after the barley harveſt, from eighty to one hundred loads an acre, and on theſe dry ſoils it does little injury to the graſſes. By this mode, the marl is on the ground at leaſt three years before the plough enters, which is far better and more durable than ploughing it directly[8].

Mr. Macro, of Barrow in Suffolk, is convinced, that about ſeventy ſquare yards or loads of marl is the propereſt quantity to be laid on an acre, pole meaſure. If more be laid on, it will be longer before it incorporates with the ſoil, and therefore before any benefit can be received from it. The effect however of a larger quantity will continue longer.

In open fields marling ſeldom anſwers the expenſe, for this is only a beginning of improvement: by going on directly with a courſe of ploughing, which cannot well be avoided in ſhiftable fields, the marl is often buried and loſt, before it mixes properly with the ſoil, eſpecially if turned in too deep the firſt earth, of which great care ſhould be taken. Marling therefore can only or chiefly anſwer on incloſed land, that can be managed as the occupier pleaſes. In that caſe, it ſhould be laid down with clover, ray-graſs and treſoil, the ſpring twelve-month before laying on the marl, and remain at leaſt ſix months after, that it may have time to ſink into the flag, before it is ploughed up, and then there will be little danger of loſing it, as it will be in ſome meaſure incorporated with the ſoil.

No pains ſhould be ſpared to break all the lumps, and to get it fine by repeated harrowings and rollings, and to have the ſtones picked and carried away, that the graſs may get through, for ſtock to be grazing upon it, which is the great and finiſhing improvement.

After the land has been got fine, and laid ſix or eight months or longer; in February or the beginning of march, break it up, and ſow it with peas. Then fallow for turneps, giving it four or five earths, with harrowings, &c. After feeding off the turneps upon the land, ſow barley, and lay it down again with clover, treſoil and ray-graſs.

Let it lay two ſummers, after which, by either folding or dunging it, if not too poor a land, there will be a good chance for a crop of wheat: after which fallow again for turneps and barley, or rape-ſeed and oats; and ſo on, always bearing in mind, that taking two following crops of corn, without a fallow or ſummer grazing, will ſoon bring new improved land to its former unpoveriſhed ſtate[9].

Let us not ſuppoſe either that Marl is of modern application in agriculture, or that no one before our times could make an experiment. That good old practical writer Walter Blith calls it a gallant manure. Obſerves that ſlipperineſs or greaſineſs is no infallible ſign of its goodneſs; but that the trueſt ſign is its *incompoundneſs*; "and if it flack alſo immediately after "a ſhower, and ſhortly after turn to duſt after it is "dry again, and doth not congeal and conglutinate like "to tough clay, but diſſolve, fear not the operation, "adventure the experimenting of it, the fruit will be "anſwerable to thy hopes."

He then relates an experiment of his own upon a miſerably poor gravelly paſture with ſome red marl, which he found in an old clay pool. On part he laid the mud from the pool, ſome he dunged, ſome he folded, the reſt he marled except one land which he did not manure at all. He brought the whole into good tillage, and ſowed it with wheat and rie mixed. The folded land produced the beſt crop, the next that which was dunged, the muddied land came in third, and the marled land laſt, though the crop on that was reaſonably good: but on that he laid nothing, he reaped nothing, not ſo much as ſtraw. The next year he ſowed barley, and upon his marled land was moſt gallant corn, ſo was his muddied land, the muckied land was the worſt by far; on the unmanured land he ſowed oats, and reaped nothing. Then he marled the lands that had been muckied, and the land which had not ſoil laid upon it; which brought forth as gallant corn as England yielded. After three or four crops the mud decayed alſo; he then marled it, and had the ſame fruit as afore ſaid. The marled land he kept in tillage nine years, without any addition of compoſt or ſoil, and had as goodly corn as ever grew; and ever ſince, with ſome ſmall addition of ſold or manure, that has out-ſtripped all the reſt[1].

It has been ſhown above that true Marl conſiſts of calcareous earth, clay and ſand in different proportions in the ſeveral varieties. The calcareous earth is involved as it were in coatings of the clay. May not this covering, by defending it from the ſudden action of the acids contained in the ground, and preventing the too rapid effects of the calcareous earth itſelf on the putreſcent and oily matter of the ſoil, account for the greater permanency of this compound than of calcareous earth alone either in a cauſtic or mild ſtate? For although it appears that marl does not form any ſalt with the acid of the air, even from long expoſure to the atmoſphere, yet it is probable that when powdered and mixed with the ſoil, it will not only unite with the acid which it may find there, but alſo attract it from the air.

This ſuggeſted to Dr. Hunter an idea that where natural marl could not be obtained, an artificial compoſition might be made, that ſhould anſwer nearly the ſame purpoſes in agriculture.

Many countries which contain no marl, have plenty of clay, where lime or chalk may be procured at an eaſy expenſe; and ſand, which is of leſs importance, and not always found in marls, is to be met with in moſt diſtricts. Clay, by the addition of water, becomes ſoft and ductile; in this ſtate it may eaſily be mixed with any portion of chalk or ſlaked lime, and a due quantity of ſand. The proportions may be different, according to the nature of the land to which the marl is to be applied. For light lands a greater quantity of clay will be proper: for ſtiff ſtrong land more calcareous earth and ſand; and for very ſtrong clay it may be ſufficient to apply a mixture of calcareous earth and ſand, with little or no clay.

The lime ſhould not only be ſlaked, but expoſed to the air, and often turned for ſeveral months.

The quantity of clay and ſand together in good marls is not great; in ſome one-third, in ſome one-fifth, in others not above one-ſixth or one-ſeventh of the whole maſs.

This artificial marl may be made, either by incorporating the chalk or lime with the moiſtened clay by kneading or beating; or elſe by throwing layers of lime or chalk and clay alternately, and then expoſing the heap during the winter to the weather, by which

[1] England's Improvements, p. 137.

means it will moulder down, and become a ſufficiently uniform maſs.

When we conſider the ſolvent power of quick-lime, this mode of producing an union between the calcareous and argillaceous earths will appear very feaſible [1].

CRAG

Is a ſort of Shell-Marl, being chiefly ſhells whole or in a decaying ſtate mixed with calcareous earth, which probably is nothing but the ſhells perfectly decayed. The benefit of it, in Suffolk, for turneps, on a poor ſand, has been found equal to that of dung; yet the greateſt effect was on a moory bottom. The Sandlings, a tract of ground in that county near Woodbridge, ſeems to be upon a foundation of this red ſhell-marl or crag. There are very large deep pits on every farm in this diſtrict, whence immenſe quantities were dug for its improvement, when firſt broken up from its waſte ſtate of heaths at 4d. an acre, to fields covered with fine crops of turneps, carrots and corn, at 5l. 10s. and 15l. an acre. The uſe of crag is however dropped here, except for taking in walk land, as they call it, or ſheep-walks. On old improved lands they never lay it on alone, but mix it with dung, earth or ouze; thinking that it makes light lands blow more [2].

Mr. Young, in his Eaſtern tour, ſays that Crag is dry and not in the leaſt ſoapy, that it does not effervesce in acids, and does not fall in water; that notwithſtanding this, all the effects and even more produced in Norfolk by ſixty, eighty and one hundred loads of Marl, are gained in Suffolk by ten or twelve of this; and that it laſts even longer, which they have diſcovered from an idea, probably a falſe one, that land once cragged, will not bear a repetition of it, except in a compoſt with dung; and accordingly they have many fields, in which it has laſted with ſuch additions, fifty, ſixty and even one hundred years. The nature of the poor ſands in that country is quite changed with it, and they gain an adheſion, which they retain for ever. It is alſo a great fertilizer, as appears from the great and ſudden increaſe in the crops after it.]

SHELLS and SHELL-SAND.

Sea-ſand and ſhells are in ſeveral parts of England uſed to great advantage, eſpecially in Devonſhire, where they are at the expenſe of fetching the ſand and ſhells on horſes backs, twelve or fourteen miles. The land on which they lay this manure, is a ſtrong loam inclining to clay.

Coral, and ſuch kind of ſtony plants which grow on the rocks, are very beneficial to land; but as theſe bodies are hard, the improvement is not the firſt or ſecond year after they are laid on the ground, becauſe they require time to pulverize them before they can mix with the earth to impregnate it. Therefore dreſſings of this kind are ſeldom uſed by tenants, who want to reap the fruit of their labour as ſoon as poſſible. But theſe manures are much better for cold ſtrong land, than for that which is light and ſandy. In ſome countries, at a great diſtance from the ſea, have been diſcovered great quantities of foſſil ſhells, which have been dug out of the earth, and uſed as manure, which have improved the ground a little, eſpecially ſtrong land.

Where the land lies near the ſea, ſo that either ſand, ſhells, corals, wrecks, or ſea-weeds can be obtained at an eaſy expenſe, they are by far the beſt kinds of manure, becauſe they enrich the land for ſeveral years; for as their ſalts are cloſely locked up, they are communicated by degrees to the land, as the heat and cold cauſes the bodies to pulverize, and fall into ſmall parts; ſo that where land and ſmaller kinds of ſea-weeds are uſed, if they are laid on land in proper quantities it will enrich it for ſix or ſeven years; but ſhells, corals, and other hard bodies, will continue many years longer.

[Mortimer mentions three ſorts of ſea-ſand uſed in the Weſt of England for manure. That about Plymouth and the ſouthern coaſts is blue, or gray like aſhes. Weſtward, near the Land's-end it is very white, and in Scilly gliſtering. On the north ſea, from about Pariſtow, and eaſtward to Lundy, it is of a brown, reddiſh, yellowiſh colour. In Falmouth, near St. Maw's there is a ſand or rather coral, that lies under the Ouſe: the red is reckoned the beſt, the blue next, and the white worſt. All theſe ſands are compoſed chiefly of ſhells. When they lie near they put on about ſixteen tons upon an acre, and leſs, as low as one ton, as the diſtance is greater. They ſpread it as ſoon as it is got home, commonly take four crops of corn from it, and then lay the land down for paſture, for ſix or ſeven years, before they plough it up again [3].

Shell-ſand is very common on the eaſt coaſt of Scotland. All along the coaſt of Fife, eſpecially about St. Andrew's. On the north coaſt of Aberdeenſhire. In Banff-ſhire, and all along the coaſt of Sutherland and Caithneſs, the ſands upon the ſhore conſiſt almoſt entirely of ſhells [4].

Cockle-ſhells are laid on ſtiff clays in the Iſle of Sheppey thirty cart-loads to the acre.

All ſhells are principally calcareous earth, and when burnt afford the beſt of lime. In a recent ſtate they are of little value as a manure, unleſs they are broken very ſmall; but in a decayed ſtate they reſemble ſhell-marl.

Upon deep loams and ſtrong clays their operation is ſimilar to chalk or marl; but upon light gravels or ſands, little benefit is to be expected from them, unleſs they are previouſly made into a compoſt with dung, clay or loam. When ſuch lands are in graſs, top-dreſſings of ſuch a compoſt will produce great effects; and if judiciouſly treated afterwards with dreſſing of any of the different earths, their value will be much improved; and the thinner the ſoil, the greater will be the profit ariſing from this management. On clay paſtures, ſhells in their ſimple ſtate will correct acidity, deſtroy ruſhes, and render the ſoil leſs retentive of moiſture.

When ſhells are burnt they are in the ſtate of lime, and muſt be uſed as ſuch.

Sea-ſand is an excellent manure on a ſummer fallow for wheat: but being repeated two or three times loſes much of its good effects, without a change of tillage [5].

Straw being ſcarce at Yarmouth, they litter their ſtables with ſea-ſand; as the bed becomes ſoiled or wet, freſh ſand is ſcattered on, until the whole is in a manner ſaturated with dung and urine; the ſtall is then cleared, and a freſh bed of ſand laid in. Thus muck of a quality ſingularly excellent is produced [6].

Sea-ſand is much uſed by florifts in Holland, where they draw their parterres into ridges before winter, and ſpread it on the tops of them.

SAND

Can ſcarcely be conſidered as a manure; it is however beneficial upon all clays, and other tenacious ſtiff lands, by ſeparating their parts, and deſtroying their coheſive quality; by which means the ſun, air, and froſt penetrate them the better.

Sand is likewiſe of great uſe upon rough coarſe meadows; nothing fines the ſurface more, or produces a thicker ſward of Dutch clover [7].

The beſt ſand is that which is waſhed out of highways, or from hills by the rains, or that which lies in rivers.

Mr. Bligh adviſes, for the increaſing of ſoil in winter, where ſheep cannot be folded, to have a ſheep-houſe to feed them in, into which he would have brought twice a week ſeveral loads of ſand out of the highways, ſtreets, or ſand-pits, which by the farmers of the ſheep's dung and urine will make an excellent manure for cold clay-lands [8].

One hundred and ſixty loads of ſand upon mooriſh paſture land, and forty upon clay land, wrought wonderful effects, and produced white clover in great abundance [9].

[9] Marſh. Norf.

In a converſation which I had with Kliyog, the Swiſs rural Socrates, as he is called by Dr. Hirzel, I found that the mixture of ſand with his ſtubborn clay land was one of his principal improvements. I examined the ſand, and could not find that it had any fertilizing qualities in the ſmalleſt degree; it acted therefore merely by ſeparating the parts of the clay.

CLAY.

As Sands are an improvement to Clays, ſo on the contrary Clays are an improvement to gravelly and ſandy lands, by making them more ſolid and tenacious. I have frequently remarked clayey and ſandy grounds lying almoſt contiguous, without any attempt having ever been made to make an experiment on this obvious interchange of ſoils.

Mr. Legrand of Guiſton-houſe near Sandwich has uſed clay with aſtoniſhing ſucceſs upon a ſoil almoſt entirely ſand: but it is not a ſingle or ſlight dreſſing that will do any good: one hundred and ſixty loads an acre make a wonderful improvement [a].

It muſt be remembered that Marl and Clay are often confounded, and that marling is frequently called claying.

The extent to which claying has been carried in the land diſtricts of Suffolk is very conſiderable. An excellent cultivator near Bury, though not on a very large farm, has carried 140,000 loads. But when this clay is not of a good ſort, that is, when it has very little clay in it, but is rather an imperfect hard chalk, there are great doubts how far it anſwers, and in many caſes it has been certainly ſpread to little or no profit. The uſual quantity is from ſixty to eighty, and ſometimes one hundred loads, of thirty-two buſhels, to an acre. The duration, and indeed the whole effect, depends much on the courſe of crops. If the plough be too freely uſed, and corn ſown too often, it anſwers badly, and the effect is ſoon loſt; but with good management it laſts twenty years. In many caſes, a courſe of fallow and rie or light oats is converted to fine barley, clover and wheat, and the produce multiplied twenty fold: but the caſes in which the return has been inadequate are not a few: and on ſoils that will yield ſainfoin, it is more profitable to cultivate that, than to clay the land for corn [b]. Probably this clay was more properly a clay-marl.

In ſtiff deep clays, where manure is not to be had in ſufficient quantities, and fuel is cheap, it may be no bad proceſs to burn ſome of the clay, which will not only break the coheſion of the ſoil and make it more eaſily cultivated, but will alſo render it leſs retentive of moiſture, and thus more friendly to vegetation. Upon thin ſoils, it is evident, any attempt at burning would be highly improper.

Mr. Belcher informs me that he has found a ſurpriſing effect in half-baking earth, which renders dead barren earth immediately productive. It muſt be only half-baked; for if fully baked, it in a great degree reverts to its priſtine ſterility. He does not mention whether it was clay or vegetable earth that he baked: the nature of the latter we know from paring and burning, but we have not had experiments enough to aſcertain the effects of burning clay.

GYPSUM, Pliſter or Pliſter of Paris

Is calcareous earth united with the vitriolic acid. It does not effervesce with acids, and is not without difficulty ſoluble in any. When heated a little below ignition, it undergoes a motion ſimilar to that of ebulliſion, from the diſſipation of its aqueous parts, and falls into powder. If taken up, when this motion ceaſes, and ſprinkled over with water, it ſoon concretes, and hardens by reaſon of its ſudden cryſtallization. It is entirely ſoluble in a large quantity of water, and may be compoſed by ſaturating the vitriolic acid with calcareous earth. What we commonly call hardneſs in water is owing to gypſeous ſelenites diſſolved in it.

Gypſum has lately been extolled in ſeveral foreign publications, as a manure of the higheſt value in Germany and particularly in America, where, according to Mr. Chancellor Livingſton, of New-York, it has produced a new era in agriculture [c].

This gentleman, after having continued his experiments three years, concludes, 1. That Gypſum in ſmall quantities has no viſible effect on wheat or rie.

2. That it is uniformly beneficial to Indian corn, unleſs in very rich or wet ſoils.

3. That it is beneficial to flax, on dry poor ſandy land.

4. That it is peculiarly adapted to the growth of clover on all dry ſoils, or even on wet ſoils in a dry ſeaſon.

5. That limeſtone pulverized has ſimilar effects with gypſum.

6. That the effects of gypſum as a manure are hardly perceptible in the vicinity of the ſea.

In the experiments of George Logan, Eſq. it appears that gypſum was uſeful even to crops of wheat and rie. This gentleman remarks, 1. That there is no difference between the American gypſum, and that which he had from Europe. 2. That it acts as an immediate manure to graſs, and afterwards in an equal degree to grain. 3. That one dreſſing will continue in force ſeveral ſucceeding crops.

He adds, that its not producing any remarkably beneficial effects, when uſed as a top-dreſſing to grain, may ariſe from two cauſes; firſt from the ſmall quantity made uſe of, which is loſt in the rough ground; and ſecondly, from the ſhort time of its application. That it has been found of advantage to Indian corn, but that it is neceſſary to apply it immediately to the corn, as it appears above ground, and that in a conſiderable quantity. That early in april is preferable to any other ſeaſon for applying it to paſture, for the graſs being juſt ſhooting at this ſeaſon, the ſmall particles of the gypſum are retained about the roots, and prevented from waſhing away. On ſtiff clay ſoils it will produce an increaſe of vegetation, but not ſufficient to pay the expenſe of the manure [d].

In general it is ſaid to have had great effects on what they call their worn out lands in America.

After having broken the plaſter into ſmall pieces by a hammer or ſtamping-mill, they reduce it to powder in a common griſt mill, and in this ſtate ſpread it upon the ground in a calm day. In miſty weather it will ſpread to moſt advantage [e].

The moſt approved quantity for graſs is ſix buſhels to the acre. It has been uſed in the ſtate of Penſylvania ever ſince the year 1778, if not ſooner, and laſts from ſeven to ten years, but its continuance very much depends on the nature of the ſoil to which it is applied [f].

By a letter to Capel Loffft, Eſq. it appears that Plaſter was come into general uſe as a manure in Penſylvania, in the year 1789; and that the grounds within ten miles of New-York, which were deemed old worn out fields, have by the uſe of this manure been ſo recovered as to ſupport fifty head of cattle, where in its former ſtate one could not live [g].

When I was in Switzerland in the year 1778, I found it in common uſe on their artificial paſtures of lucerne, &c. at leaſt in the neighbourhood of Geneva.

It is ſaid to have been diſcovered as a manure in Europe by Mr. Meyer, a clergyman of uncommon merit in Franconia, in the year 1768. It has been applied with ſignal ſucceſs in Germany, Switzerland, France, &c. and if it has not met with the ſame ſucceſs in England, it muſt probably be, becauſe the calcareous principle prevails here ſo generally [h].

Sir Richard Sutton and others who have tried gypſum here, have not been able to trace any effects from it. Mr. Proctor Anderdon of Henlade, Somerſetſhire, concludes from ſome experiments, that on many plants, or in many ſoils, gypſum powder will have no effect; but that it has ſome effect on old clover in a loamy ſoil; and that a greater effect may reaſonably be ex-

pected from it, when applied to younger plants of the ſame ſort or nature.

This agrees with the American accounts, Clover there being the crop more benefited by gypſum than any other. Calcareous earth indeed is generally acknowledged to be favourable to the growth of clover; but the addition of the vitriolic acid, a ſuſpected poiſon in agriculture, would naturally have induced the agricultural chemiſt to have rejected gypſum as a manure[a].

According to Kirwan, the rationale of its effects may be deduced from its extraordinary ſeptic power, for it is found to accelerate putrefaction in a higher degree than any other ſubſtance.

Mr. Smith, of Woodſtock near Sittingbourne in Kent, affirms (in the year 1795) that from the trials he has made of it for three years paſt on chalky and dry calcareous ſoils, laid down with ſainfoin or clover, the effects have been aſtoniſhing, and entirely correſpond with the American accounts[b].

He applied ſix buſhels to an acre; the Americans ſeem to have been uſing ſmaller quantities, even ſo low as one buſhel to an acre.

Mr. Belcher recommends ſix buſhels of gypſum powder to be ſown on an acre, from the middle of april to the middle of may, and affirms that it has aſtoniſhing effects on clover, ſainfoin and other leguminous plants, commonly called artificial graſſes.

In the few inſtances where gypſum has hitherto been uſed in England, it is ſaid to have produced aſtoniſhing effects in ſome, in others no viſible advantage has been derived from it, and in ſeveral it ſeems to have done miſchief.

Upon lands where no ſtimulating ſubſtance has been applied, and which contain little or no calcareous earth, gypſum will be a good manure: accordingly in America, where the ſoil in moſt places is compoſed almoſt entirely of vegetable earth, from decayed herbs, leaves and branches, and where ſcarcely a particle of calcareous earth is to be met with, gypſum will produce good effects: but upon lands which have been long in a ſtate of cultivation, which have been frequently manured with ſubſtances containing much alkaline matter, its effects will not be perceptible: but where acid prevails, its bad effects will be viſible at once. Gypſum therefore is a manure that can ſeldom be uſed with advantage in this country upon arable lands; there being few ſituations in which the ſoil does not either contain calcareous matter in itſelf, or has received it as a manure.

Ashes,

Of all kinds of vegetables, are an excellent manure or top-dreſſing for land.

Pot-aſh, or *fixed Vegetable Alkali*.

In places far removed from the means of improvement, a ſubſtitute for common manures, that is of eaſy carriage, and can be had at a moderate expenſe, muſt be valuable.

From experiments that have been made it appears that 2000lb. of pot-aſh are ſufficient for an acre of ſtrong land; for lighter ſoils much leſs is required, if laid on by itſelf; on theſe however a compoſt of this and oil, incorporated with mould, will be the beſt way of employing it. Upon ſtrong clays and deep loams however, it ought always to be applied by itſelf. When the expenſe of carriage is conſidered, pot-aſh will often be found a cheaper manure than lime. In one reſpect it is ſuperior, for the union of pot-aſh with all the different acids forms a neutral, which is in ſome degree uſeful in vegetation; whereas when lime meets with the vitriolic acid, it is almoſt entirely loſt.

A conſiderable part, if not the whole of what is uſed in manufactures, glaſs excepted, will be uſeful as a manure, after the purpoſe of the manufacture is ſerved; particularly in bleaching, the alkali of which will be found improved, in conſequence of the mucilage or oil which it has imbibed from the cloth.

Kelp is a mixture of foſſil alkali or ſoda, and ſea-ſalt, beſides earth or ſtones. All marine plants abound with this alkali.

[a] Wilkinſon in V. ann. 21. 202.
[b] Young's Ann. 24. 359. and 25. 334.

The operation of kelp depends upon the ſame principles as lime, pot-aſh, &c. Like them, it produces the beſt effects upon deep loams or clays; and the benefit will be ſtill farther increaſed, if lime be made uſe of along with it. Kelp ſhould be broken very ſmall with large hammers, or by paſſing it through a mill.

Bleacher's aſhes or refuſe, conſiſt principally of the hard undiſſolved parts of pot-aſh, kelp, weed-aſh and barilla. Alone they are too ſtimulating, and ought never to be uſed but with earth or earth and dung; they anſwer well with blood, garbage, and putrid animal ſubſtances. They are generally laid upon fallows for wheat. The greateſt advantage derived from them is upon clay or deep loams. Upon ruſhy grounds, or coarſe wet meadows they will be found particularly uſeful.

Soap-aſhes are in ſome meaſure the ſame as the refuſe of bleach-fields. They principally conſiſt of lime, which is uſed by ſoap-makers to deprive the alkaline ſalts of their fixed air: the addition of lime to ſoap-aſhes is therefore unneceſſary. They are generally made into compoſts with earth and well fermented dung, in the proportion of two loads of dung to one of earth; the aſhes are then added, in the quantity of one load to ten of this mixture, turning and incorporating the whole completely.

The quantity neceſſary for ſtrong clays or deep loams is ten cart-loads to an acre. If the dung has been well fermented, perhaps the moſt profitable way of uſing this compoſt will be as a top-dreſſing harrowed in with the grain; taking care however that the cauſtic quality of the aſhes is properly blunted by a ſufficient mixture of dung and earth.

Theſe aſhes, when beat ſmall, may be made into a rich compoſt with oil and earth, and uſed as a top-dreſſing for young crops. They will deſtroy flugs and vermin of every deſcription: and are therefore highly valuable on lands where the early wheat is injured by the worm. Laid upon graſs-lands in the end of autumn, this manure produces a deep verdure during the winter, and an early vigorous vegetation in the ſpring; it is therefore particularly calculated for cold wet paſtures.

Soap-ley conſiſts of alkaline ſalts and oil, and is produced by the ſolution of ſoap in water. The quantity of this that is daily waſted is immenſe, and forms a contraſt to the ſtrict economy of the Chineſe, where even the ſoap-ſuds of the barbers are ſaid to be carefully preſerved. It ſhould all go to enrich the compoſt dunghill.

Fern-aſhes. No vegetable affords ſo much pot-aſh as Fern, but it is better to uſe it as litter for manure, than to burn it for the aſhes.

Fern-aſhes ought not to be uſed by themſelves, unleſs upon the heavieſt and deepeſt ſoils, for corn-crops, or upon wet ſour meadows, upon other lands they ſhould be mixed with dung and earth.

Fern ought to be cut before it decays, either for litter or the aſhes; for all plants that contain much fixed alkali, when withered, are liable to be robbed of it by every ſhower that falls[a].

Peat-aſhes are principally employed as a top-dreſſing upon clover or clay-lands, and when rain falls immediately, the crop is benefited by the uſe of them: but upon thin ſoils, when dry weather ſucceeds, they produce no effect, or even do harm, eſpecially if they have been prepared from the richeſt ſort of peat.

The peat of ſome moſſes contains a conſiderable quantity of fixed alkaline ſalts, whilſt that of others contains ſcarcely any. All peats however agree in affording more or leſs alkali when burnt, and the value of their aſhes depends entirely upon the quantity of fixed alkali which they contain; for the burning of peat, like every other vegetable ſubſtance, is utter deſtruction to its other component parts: the oil being diſſipated in ſmoke, and the vegetable earth rendered entirely uſeleſs.

The fixed alkali contained in peat is from a twenty-ſecond to a thirty-ſecond part of its weight. Where

[a] Bath papers, 1. 153.

the peat is so rich as to afford a twenty-second part, it is an object to burn it for the ashes; but less trouble and very small expense will subject it to the process of fermentation, by which the oil and vegetable earth will be saved. This however can be done only in the neighbourhood of a moss, the carriage of the peat in substance to any considerable distance being too heavy an expense.

Eight or ten bushels of rich peat-ashes are sufficient to dress an acre. They should be laid on in the spring, before the plants have attained any great size, in wet or at least cloudy weather. Or they may be sown and harrowed in with the grain; in which case a greater quantity will be requisite than when they are used as a top-dressing[1].

Ashes burnt from fat black peat, such as is dug about Newbury in Berkshire, and in some parts of the Isle of Ely, are so rich, that farmers are afraid to lay them on barley, nor do they dress their wheat with them till late in the spring. If sown too thick, and a dry season should ensue, they are apt to burn the tender fibres of the corn. They destroy slugs on peas, &c. better than any thing[2].

Pease-ashes are an excellent improver of grass lands, particularly of clover and sainfoin: the quantity from fifteen to twenty-five bushels, according to the condition of the land. They are bought on the spot from 2d. to 4d. a bushel, according to their goodness.

This manure has been known in Berkshire near a century; they fell into disuse from having been laid on in quantities too great, but are now generally adopted by every farmer within a reasonable distance of the Berkshire peat-mosses[3].

Peat-ashes are delivered on the land, about Dunstable, at 4d. the bushel, struck: forty bushels is a complete dressing for an acre, and costs about 16s. They greatly improve dry chalk soils, but do little good on wet land or cold sward, or on hot sandy lands.

Peat-dust, or peat ground to powder, answers equally well with the ashes, in the same quantity. It is esteemed the best manure for asparagus, onion beds, and flowers, mixed with dung; and destroys thistles, if laid on in sufficient quantity, or repeated[4].

Wood Ashes are useful as a manure, principally on account of the pot-ash which they contain. The ashes of fir, pine, &c. have very little of it; but oak, ash, and most of the hard woods abound in pot-ash.

Except upon the strongest and most tenacious soils, the rich kinds of wood ashes are too stimulating, and are best used in a compost with earth and dung or any animal substances.

They effectually correct sour soils: consequently upon poor meadows or ruthy grounds, they produce effects similar to lime; and if mixed with quick-lime, their beneficial effects will be heightened.

Coal Ashes are well adapted to clays and deep loams, by breaking the tenacity of the soil. On light soils they should never be used but in form of compost with earth, or earth and dung. Where much sea-weed, or the refuse of mustard manufactures can be obtained, an excellent top-dressing may be made with these, the shells of the mustard-seed and lime[5].

Coal-ashes cost in London from 6s. to 14s. the waggon-load. They are distributed on the land about Dunstable with a shovel from a cart or wheelbarrow; but the common way is to sow them by hand.

From fifty to sixty bushels is a complete dressing for a statute acre. They succeed well sown on clover in march or april, on dry chalk lands; and do much good to sward, applied during any part of the winter or spring. They are never used, about Dunstable, on wheat. In very dry seasons they do little good except on cold sward, which they always improve. They require rain after being sown to set them to work[6].

Coal-ashes are of great use in the kitchen garden, where the natural soil is too strong and stubborn.

Mortimer and Bradley both agree that they are one of the best and most lasting manures for cold lands; and the surest to kill worms, &c.

Even so early as Worlidge's time they were brought to form an excellent compost with horse-dung, and to kill moss and rushes in wet grounds.

Ashes from kilns of any sorts, but particularly where wood, straw or furze are burnt, are a good manure for most kinds of soil[7]. In short the ashes of all vegetables are an excellent manure; so that where ground is overrun with bushes, brambles, heath, &c. if these be grubbed up in summer, and spread abroad to dry, then gently consumed to ashes, and these ashes spread on the land, they will greatly improve it. [See more of this under *Paring and Burning*.

Sea-Salt.

It is a subject of dispute whether this, or any other neutral salt be of any use as a manure. We have many experiments and conclusions on both sides: in those which are favourable, it was observed, that it, the part most loaded with bittern, that was used.

From Sir John Pringle's experiments, it appears that sea-salt, if below, or exceeding a certain proportion, is a powerful septic. How whatever promotes putrefaction must be a manure. But the septic quality of sea-salt is far inferior to that which the bittern or muriate of magnesia, and the muriate of lime, both which abound in the refuse of sea-salt, possess. These are perhaps the most septic of any bodies with which we are acquainted, and from their extreme attraction for water, have a tendency to keep land perpetually moist. Reasoning then from the qualities of bodies, we should esteem the *refuse* of salt as itself, a powerful manure. But applied in such quantity as to saturate the soil, it would kill every plant, and continue to prevent vegetation, until its excess be washed away.

However this may be, so much is certain, that sown upon pastures, salt or its refuse, if it did not increase the herbage, would at least render it highly palatable to cattle.

Nitre or *Saltpetre*, as appears from Dr. Home's experiments, mixed in the proportion of one ounce to six pounds of earth, rather retards than promotes vegetation; yet when added in small quantities diffused in water, it promoted vegetation considerably.

When a plant is so situated, that it is compelled to draw up any salt into its substance; or when the roots cannot extend themselves without coming in contact with saline particles, it soon languishes and dies: yet every process by which the saline ingredients in a soil are made to decompose, and assume new arrangements, contributes highly to its fertility. Of these no process is more beneficial than that by which nitre is formed. Although therefore this salt should not of itself greatly promote vegetation, yet the putrefactive process excited in the soil, and which generates nitre, is the real cause of its fertility.

Any salt whatever that is capable of exciting putrefaction, and that powerfully attracts and retains moisture, may be usefully applied as a manure. No salt promotes vegetation by entering into the substance of plants, but acts upon the soil itself. Many other salts possess the properties of nitre in a greater degree, and the most beneficial of them may be procured at small expense. All salts with metallic bases, being of a caustic nature, must be excepted[8].

Refuse salt may be had in London for 3l. 10s. the ton. It is therefore much cheaper than oil-cake. Would it not answer better? Might it not be sown and harrowed in march or april on land intended for turneips? but certainly never with the seed, as oil-cake is. There can

be no doubt of the propriety of throwing ſalt into all dung-hills, when they are turned over; or when the yard-dung is ſhovelled on to heaps. Suppoſe ten loads to be the quantity of dung for an acre; five, with a quarter of a ton of ſalt, would probably be better; but great attention would be neceſſary in mixing and ſpreading [a].

The reſult of ſome experiments made by Mr. Young were highly in favour of ſalt when diſſolved in water, and added to dung: and ſuggeſt an important leſſon for the addition of ſalt water to dung-hills [b].

Mr. Legrand, of Guilton-houſe, near Sandwich, having tried ſoul ſalt upon a ſandy ſoil, found ſixteen buſhels to be a proper quantity for an acre. He uſed it upon a barley tilth; ſowing the ſalt immediately after the barley. The event was perfectly ſatisfactory. It is noxious both to weeds and vermin [c].

Salt remaining after it has been uſed for preſerving pilchards, has been employed with great ſucceſs in Cornwall, in the cultivation of turneps [d].]

COMPOSTS

In huſbandry and gardening ſignify ſeveral ſorts of ſoils or earthy matter, lime, dung, &c. mixed together, in order to make a manure for aſſiſting the natural earth in the work of vegetation.

Compoſts are various, and ought to be different, according to the different nature or quality of the ſoils which they are deſigned to meliorate: and according as the land is either light, ſandy, looſe, heavy, clayey, or cloudy. A light looſe land requires a compoſt of a heavy nature, as the ſcouring of deep ditches, ponds, &c. A land that is heavy requires a compoſt of a more ſprightly nature, that will inſinuate itſelf into the lumpiſh clods.

For Gardens.

The great uſe of compoſts in gardening is for ſuch plants as are preſerved in pots or tubs; or in ſmall beds or borders of flower-gardens. As ſome plants delight in a rich light ſoil, others in a poor ſandy ſoil, and ſome in a loamy ſoil; there ſhould be different compoſts prepared, in all thoſe gardens, where a great variety of plants are cultivated: and this is much more neceſſary in countries at a great diſtance from London, than in the neighbourhood of it, becauſe there is ſo great variety of lands, within ten miles round London, which have been ſo long dreſſed and cultivated, that a ſupply of earth fit for all ſorts of plants, may be eaſily procured; but in ſome places which are at a diſtance from large towns, it is very difficult to procure a quantity of earth proper for the choicer ſorts of flowers and plants; therefore the compoſts will require more care, and ſhould be mixed a conſiderable time longer before they are uſed; that they may have the advantage of heat and cold, to meliorate and improve them; and ſhould be frequently turned over, that the parts may be well mixed and incorporated, and the clods well broken and divided.

Almoſt every one who has written on this ſubject, has directed the procuring the upper ſurface of earth from a paſture ground, as one of the principal ingredients, in moſt compoſts for plants, which is certainly a very good one, provided it has time to meliorate before it is uſed: for if this is mixed up haſtily, and put into pots or tubs, before it has had a winter's froſt, and ſummer's heat, to looſen the parts effectually; it will unite and cake together, ſo hard, as to ſtarve the plants that are put into it. For all earth when put into pots or tubs, is much more apt to bind, than when it is in beds; therefore ſhould be in proportion made looſer, according to the nature of the plants for which it is deſigned, than when it is intended for beds or borders. So that if this earth from a paſture, cannot be prepared and mixed at leaſt one year before it is uſed, it will be much better to take the earth of a kitchen-garden which has been well wrought and dunged; but this ſhould be clear from all roots of trees and bad weeds. If this earth is well mixed with the other compoſts ſix months, and often turned over, it will be fitter for pots and tubs, than the other will in twice that time, as I have frequently experienced. This earth being the principal ingredient in thoſe compoſts deſigned for ſuch plants as require a rich ſoil; the next is to have a quantity of very rotten dung, from old hot-beds; or for thoſe plants which delight in a cool ſoil, a quantity of rotten neats-dung is preferable. The proportion of this muſt be according to the quality of the earth; for if that is poor, there ſhould be one-third part of dung, but if it be rich, a fourth part or leſs will be ſufficient. Theſe, when well incorporated and the parts divided, will require no other mixture, unleſs the earth is inclinable to bind, in which caſe it will be proper to add ſome ſand or ſea-coal-aſhes to it; if ſea-ſand can be eaſily procured, that is the beſt, the next to that is drift-ſand; but that from pits is by no means proper. The proportion of this muſt be according to the nature of the earth, for if that is ſtiff, there muſt be a greater proportion uſed, but this ſhould not exceed a fifth part, unleſs it is very ſtrong, in which caſe it will require more, and a longer time to lie, and muſt be often turned over before it is uſed.

The next compoſt, which is deſigned for plants which do not require ſo good earth, and naturally grow on looſe ſoils, ſhould be half of the before-mentioned earth from a paſture, or that from a kitchen-garden; and if theſe are inclinable to bind, there ſhould be a third part ſand, and the other part rotten tan, which will be of great uſe to keep the parts divided, and let the moiſture paſs off.

The compoſition for moſt of the ſucculent plants, is prepared with the following materials; the earth from a common, where it is light, taken on the ſurface, one half, the other half ſea or drift-ſand, and old lime-rubbiſh ſcreened of equal parts; theſe, well mixed and often turned over, I have found to anſwer better than any other compoſt, for moſt of the very ſucculent plants.

The other ſort of compoſt, which is deſigned for plants that delight in a very looſe, light, rich earth; ſhould be made of light earth taken from a kitchen-garden, which has been well dunged, and thoroughly wrought, like thoſe near London, one half; of rotten tanners-bark one third, and the other part mud from the ſcouring of ditches, or from the bottoms of ponds, where the ſoil is fat: but this mud ſhould lie expoſed in ſmall heaps a whole year, and be often turned over before it is mixed with the other, and afterwards frequently turned and mixed, for eight months or a year before it is uſed.

In all mixtures, where rotten wood may be required, if the rotten tanners bark, which is taken from old hot-beds is uſed, that will anſwer every purpoſe of the other; and wherever ſand is neceſſary in any compoſt, the ſea ſand ſhould always be preferred to all other; but this ſhould not be uſed freſh, becauſe the ſalts ſhould be expoſed to the air, which will looſen the particles, and thereby render them better adapted for the nutriment of vegetables.

There are ſome who have directed the uſe of rotten leaves of vegetables, as an excellent ingredient in moſt compoſts; but from many years experience, I can affirm, they are of little uſe, and contain the leaſt quantity of vegetable paſture, of any dreſſing which is uſed. Others, who never have had any experience in the culture of plants, have directed different compoſts for almoſt every plant: and theſe compoſts conſiſt of ſuch a variety of ingredients, as greatly to reſemble the preſcriptions of a quack doctor; no perſon who has been converſant in the buſineſs of gardening, could be guilty of ſuch groſs abſurdities: for it is well known, that a few different compoſts will be ſufficient for all the known plants in the world. But thoſe who pretend to give direction for the culture of plants from theory only, begin at the wrong end, for the true knowledge of gardening or agriculture, muſt be from experience.

In making any compoſt, great care ſhould be had, that the ſeveral parts are properly mixed together, and not to have too much of any one ſort thrown together; therefore, when three or four ſeveral ſorts are to be mixed together, there ſhould be a man or two placed to each ſort, in proportion to the quantity of each,

[a] Young's Ann. v. 378.
[b] Idem, v. 143.
[c] Idem. v. 144.
[d] Idem. 27. 200.

for if two parts of any one ſort are requiſite to be added, there ſhould be two men put to that, and but one to each of the other: and theſe men muſt be careful to ſpread each ſort in ſuch a manner over each other, as that they may be exactly mixed together. Another thing which ſhould be obſerved is, never to lay theſe compoſts in too large heaps, but rather continue them in length, laying them up in a ridge, ſo that the ſun and air may more eaſily penetrate through it: and, as theſe compoſts ſhould (if poſſible) be made a year before they are uſed, they ſhould be frequently turned over, which will prevent the growth of weeds, and expoſe every part of the heap equally to the ſun and air; and the more they are expoſed to the influence of theſe, the better will they be prepared for vegetation.

[*For Fields.*

Something has been already ſaid under ſeveral of the preceding articles, on the application of various compoſts in agriculture, but more muſt be added on a ſubject of ſo much importance, ſo little underſtood, and even yet ſo partially practiſed, though it is gaining ground every day.

Compoſts are uſually made by mixing various ſubſtances with ſtable or yard dung; and hence in ſome countries are called Mixens. The moſt common materials for this purpoſe are turf pared from waſte places, virgin earth, peat earth, lime, the ſcourings of brooks, ponds, and ditches, weeds, rubbiſh of buildings, coal-aſhes, &c.

That dung alone, properly managed and applied, is a moſt valuable manure is beyond all doubt, but it certainly is not equally uſeful in all ſoils and ſituations. It is much better calculated for active than inactive ſoils. On limeſtone, chalk, &c. it meets with abundance of active materials, but upon clays, deep loams, &c. it operates beſt in conjunction with lime or ſome other ſtimulating ſubſtance.

When dung is intended for a compoſt, no attempt ſhould be made to add a large quantity of lime, earth, &c. till it is properly fermented, every addition of this kind checking the fermentation. The lime, earth, &c. ſhould be added after the fermentation is finiſhed, and the whole then carefully mixed and laid up together. In a few days a ſecond fermentation will come on, and if the mixture has been properly turned over and thoroughly incorporated, it will be fit for uſe in a month or ſix weeks.

Some judgment and attention will be requiſite, with regard to the quantity of lime and other active principles employed: for if the quantity be ſmall, their action upon the rich ſubſtances in the dung will be partial and imperfect; and if too great, a conſiderable loſs may be ſuſtained by their over action. If the quantity of earth alſo be ſuch as to preſs the dung too hard, the air will be excluded and the ſecond fermentation be impeded or prevented. It is certainly a right method to lay a good coat of earth as a foundation for the dunghill, into which the moiſture of the dung may ſoak down: and it is no bad way to make a heap of ſuch ſubſtances as can be readily obtained, apart from the dung, and to throw the moiſture of the dunghill and the urine of cattle over it[a].

Compoſts are formed in various ways. In ſome places, where there is a head or foot ridge, too high to admit the water to be rapidly diſcharged from the field, they plough it, then fill it full of lime, dung, or both, and after frequent ploughings, ſpread it upon the field. After the lime is ſufficiently mixed, the earth may be gathered into a heap with the ſpade, and mixed with dung; or the whole operation may be performed with the ſpade, which is ſtill better.

The earth or mud gathered from the bottom of ditches is excellent for compoſts. It is uſually the lighteſt part of the ſoil carried thither by water, and frequently contains a portion of vegetable matter. To this may be added the cleanings of roads, eſpecially where they are laid with limeſtone. One of the beſt materials for compoſts is Peat. This fills up the pores of a ſandy or gravelly ſoil, without diminiſhing its fruitility. Even when applied by itſelf to ſuch ſoil, peat increaſes its fertility. But in a hard clay ſoil, it ſhould be fermented with lime, or dung, or both, and frequently turned to make it mix properly. Without this precaution it dries, hardens, and cannot be properly mixed afterwards.

In making compoſts, if only one ſort of manure be uſed, it is only neceſſary to put the manure and earth in alternate layers in a long ridge; and top it ſo that rain may not waſh through it. When both lime and dung are uſed, a layer of earth ſhould be interpoſed between every two beds of lime and dung: for lime, if mixed with dung in the firſt ſtage of its putrefaction corrodes and diſſipates its effluvia. After the firſt fermentation of the dung is completed, the whole ſhould be turned to mix the ingredients; and this operation ſhould be repeated until the maſs be ſufficiently pulverized; which is done by cutting the compoſt with a ſpade in perpendicular ſlices.

All the weeds ſhould be collected from the neighbouring fields, before they run to ſeed, and mixed with the compoſt. The weeds alſo that grow upon it, ſhould be buried down in it.

Such compoſts may be uſed for any crop; and when ſufficiently pulverized are excellent for a top-dreſſing to paſture; the parts being gradually crumbled down, and beaten into the ſoil by the feet of cattle or waſhed in by rains[b].

Some are of opinion that no advantage reſults from mixing dung with earth: a bottom of earth however muſt always be uſeful to detain the moiſture that flows from the dung. Quick-lime mixed with the dung is uſeful, by keeping the mucilage in a proper ſtate, and preventing the putrefaction from proceeding too far.

The following is a good method of making a Compoſt. In a field conveniently ſituated, plough and harrow a headland, till the ſoil is well divided and in fine tilth; then take a cart-load or forty buſhels of lime freſh from the kiln, and place it in little heaps, about a buſhel in each, along the middle of the headland, at four feet diſtance from each other. Cover the heaps with four or five times their quantity of pulverized earth, and pat it down cloſe with the back of a ſhovel, ſo as to exclude both rain and air. In a few days the moiſture of the earth will have diſſolved the lime, and reduced it to a powder. If the heaps have any fiſſures in them, they ſhould from time to time be filled up, by having more earth thrown upon them, and patted down cloſe. When the lime is perfectly reduced to a powder, that and the earth muſt be chopped down with a ſpade, and intimately blended together. This is moſt conveniently done in form of a long bank or ridge, in the middle of which a large furrow or opening muſt be made ſufficient to receive five cart-loads (forty buſhels each) of good ſpit dung; when the earth and lime muſt be thrown over the dung ſo as to cover the whole. In this manner it muſt lie ſome months, or till the dung is in a ſtate of diſſolution. When arrived at this ſtate, it muſt be turned over again, well mixed, and formed into a heap or clamp to be kept for uſe. Earth, lime and dung thus managed, conſtitute an unctuous maſs of great fertility[c].

In Eſſex they are particularly induſtrious in this practice, where, as the ſkirts of incloſures ſeldom produce any corn on account of the ſhade and dripping of the hedges, and what it does produce is of little value, becauſe the birds prey upon it, they generally ſink theſe borders at leaſt a foot deep, and mix them into compoſt, for the benefit of the reſt of the land, which is more expoſed to the ſun, and leſs liable to be preyed upon by birds.

Next to theſe borders of incloſures or banks of roads, the ſcouring of old ditches, the mud of ponds, and ſediments of ſtagnant waters are valuable, eſpecially on graſs land; and a ſmall mixture of lime is well beſtowed upon it. Any maiden earth, with one ſeventh part of lime, and another ſeventh of rotten dung is good manure for moſt kinds of paſture[d].

In

In Norfolk the making compoſt dunghills is a general practice. The principal ſource of them is the ſhovelling of ditches, which is found there to be ſingularly fertile. It is not the ſediment of water from the incloſures, but conſiſts entirely of dead weeds, leaves of the hedge, and the mouldering of the bank and ſides of the ditch. The moſt barren ſubſtratum expoſed a few years in the face of a ditch bank, is changed into a rich black mould. Perhaps the ſea air, acting upon a looſe porous ſoil, may aſſiſt in producing this change. Other ſources of manure are uſeleſs turf, the backs of ditch-banks, the borders of fences in general, the ſides of lanes, the nooks of yards, &c. which in many places are ſuffered to remain the nurſery of weeds. Theſe are turned up into ridges, to rot the roots of the graſs and weeds, and to receive the melioration of the air; which done, it is carted in the ſeaſon to the dung-heap to be incorporated with it[1].

An effectual mode of raiſing a large quantity of compoſt manure, is to bed the farm yard about two feet deep with earth, and on this to cleanſe the ſtables, cow-houſes, hog-ſties, &c. and to move the cribs in which looſe cattle are fed with ſtraw about it. This bed of earth will retain the urine, ſo that when the whole is mixed together, it will all be nearly of equal goodneſs, and admirably adapted to gravelly and looſe ſoils in general, through which the eſſence of dung alone will be waſhed in one ſeaſon; a top-dreſſing of ſoot, pigeon's dung, &c. will laſt but one crop, and very rotten pure dung is little better.

On binding pebbly loams, having ſo ſtrong an adheſion, as to be what farmers juſtly call unkindly land, having the tenacity of clay without any of its excellencies, ſmall quantities of dreſſings however rich, are of little benefit; a pound of the eſſence of dung might be ſo faſt locked up in a large clod as to be rendered totally uſeleſs for a whole ſeaſon: a rich top-dreſſing of ſoot, &c. is often quite loſt on ſuch land. Nothing does ſo well with it as compoſts not kept long, carried on in very large quantities. Perhaps twenty loads on an acre may do little good, when forty loads may be effectual: for there muſt be quantity enough to keep the clods and looſe earth from uniting, or elſe the manuring is of little ſervice. Small quantities alſo raiſe no fermentation, and it is obvious of what conſequence a ſtrong fermentation completed in the ſoil muſt be to ſuch land.

Another method of raiſing compoſt dunghills is by making them into clamps. Make a layer of hedge earth from a grubbed border, two feet deep and about twelve feet ſquare, in the beginning of november; the quantity of earth will be about twenty-ſix loads of ſixteen buſhels each: on this clean all the yards and ſheds. The yard, not being bedded with earth, ſhould be well littered to ſoak up the urine, and to be made into dung by the hogs and looſe cattle; this may be cleaned once a fortnight, and the ſheds once a week; and piled regularly on the foundation of earth, until the heap is about ſeven feet high; and when one clamp is thus filled up, another foundation of earth may be laid adjoining to it. In order to drench the compoſt, the ſlowings of the heap ſhould be prevented from running off, and thrown up occaſionally on the heap.

By thus piling the compoſt in clamps, it will be in very good order for arable land early in the ſpring; which will not be the caſe, if it be left to be trodden flat over the whole yard, and every particle to be waſhed by the rain. Fermentation goes on much quicker in this method, and it would be better ſtill if the heap were made under a roof, to keep off all water but what is thrown up.

Another advantage of this method is, that any part of the compoſt may be uſed, by taking a diviſion of the ſtill that has been the longeſt finiſhed[2].

All ſorts of animal ſubſtances mixed with earth, litter, or any vegetables, make a rich compoſt. Sawduſt mixed in layers with the blood and offal of a ſlaughter-houſe, and incorporated till the whole becomes a moiſt ſeed mals is a rich compoſt. Two loads of it, with three loads of earth will be ſufficient for an acre of wheat or ſpring-corn. Being a kind of top-dreſſing, it ſhould be put on at the time of ſowing, and harrowed in with the grain.

This manure is beſt adapted to lands of an open texture. Tough clays require lime and plenty of dung to break the coheſion of their parts. As this compoſt takes up little room, it is very convenient for the uſe of ſuch farmers as are obliged to bring manures from a diſtance. It is alſo extremely rich, and will probably continue longer in the land than yard or ſtable dung.

All animal ſubſtances being of the ſame nature, the refuſe of whale-fat, after the oil is boiled out, will make a rich compoſt with freſh dung, which will reduce the blubber ſpeedily into a putrid ſtate, or with earth and dung. Having marked out the length and breadth of your intended dunghill, make a layer of earth (as moor-earth, or that of ant-hills) about a foot in thickneſs; over this put a layer of yard or ſtable dung of the ſame thickneſs; then a layer of blubber; and over that another layer of dung. Repeat the operations till the heap be raiſed about ſix feet, then give it a thick covering of earth, and coat the heap with lath. In about a month turn the whole in the uſual manner; and when turned, coat with earth as before to confine the putrid effluvia. In a month or two the heat will be conſiderably laſſen, when it ſhould have a ſecond turning. This operation muſt be repeated at proper intervals, till the whole becomes a uniform putrid maſs. In general this compoſt ſhould not be uſed till it is a year old. The heap muſt be guarded from dogs, ſwine, &c.

This compoſt may with great advantage be applied to all purpoſes where good rotten dung is required. It is excellent for cabbages and for meadow ground. One hogſhead of whale refuſe will make eight loads of dung; and muſt be of importance to thoſe farmers as lie at a diſtance from manure, but within reach of thoſe places where train-oil is prepared. We ſhall hope therefore not to hear any more of this precious oil being thrown into the ſea[3].

It is obvious that the refuſe of all ſorts of fiſh, and fiſh itſelf when in ſhoals too great for conſumption may advantageouſly be made into a compoſt in the ways above deſcribed.

Theſe are local advantages, and are mentioned principally with a view to put farmers upon ſearching diligently for ſuch ſubſtances as may be within their reach, that are capable of aſſiſting the finer and more common dung hill, upon which in many places they rely wholly, however inadequate to their wants. Abundance of good manure, properly managed, being the life and ſoul of huſbandry.

Where there is a deficiency of materials for making good compoſts proper for the ſoil, in many caſes a mixture of different ſoils may anſwer the purpoſe. Thus where clay predominates, the addition of ſand, where it is happily within reach, is often ſufficient to cultivate fertility; and where ſand prevails, the addition of clay or chalk will anſwer the ſame purpoſe. Gravel enriches peat moſs, and that in return improves gravel. The farmer therefore ſhould ſearch every where, above ground and below for ſuch ſubſtances as may improve his ſeveral ſoils by a due mixture.

Top-Dreſſings.

Much has been already ſaid about theſe under ſeveral of the foregoing articles. They are pounded ſoot, rape cake, pigeon's dung, peat aſhes, and the like, but well-rotted dung, and compoſts in general when ſufficiently mixed and pulverized by ſeaſons, turning, may be uſed in the ſame way.

Top-dreſſings anſwer particularly well on crops that tiller, as wheat and barley; and when theſe are beat and backward in the ſpring, in conſequence of a bad ſeed-time, immoderate wet, ſevere froſts, and other cauſes, help them prodigiouſly by quickening their vegetation, and thus enabling them to cover the ſoil

[1] Houlton's Eſſays, p. 150, 154.

from

from the enſuing drought of ſummer. They are peculiarly applicable to poor, light, ſandy and gravelly or limeſtone lands.

The advocates for top-dreſſings in preference to ploughing in manure affirm, that when a conſiderable quantity of dung is laid upon land, and mixed with the whole ſoil, a great proportion of its richeſt ſalts will be carried down by rains, and not only be loſt to the preſent crop, but if the ſub-ſoil be of a looſe and porous nature, will very ſoon eſcape beneath the reach of the plough. Whereas if ſtable-dung and other enriching manures were mixed with lime or other active ſubſtances into a compoſt, and thus employed as a top-dreſſing, a much ſmaller quantity than is uſually applied might probably be found ſufficient. By thus laying manures upon or near the ſurface, they ſink by ſlow degrees, their beneficial effects are exerted upon the crop in their paſſage downwards, and very little, if any, of the fertilizing parts penetrate beyond where they are uſeful.

Top-dreſſings however are frequently attended with great expenſe; their effects are not permanent, and in very dry ſeaſons they d. little or no good[a].

When top-dreſſings are applied, the nouriſhment of the plants only is conſidered, no regard being had to looſening the earth; they are not therefore ſufficient for heavy lands. Stiff loams and clay require lime and dung to break the coheſion of their parts.

Beans alſo, and tap-rooted plants in general require ſuch manures as are worked into the land by the plough; for top-dreſſings operate but a little way within the ſurface, except on thin ſoils, where they are certainly of great uſe. They are very beneficial on turneps, by puſhing the young plant haſtily into rough leaf, and thereby ſecuring it againſt the fly, but no farther[b]. See the articles *Soot*, *Aſhes*, &c. &c.

PARING and BURNING, BURN-BAKING, or DENSHIRING,

Is not only a very great, but a very ancient way of improvement, according to Mortimer, who treats largely on the ſubject. It is not proper, ſays he, for rich ſoils, or dry ſtony lands, or chalky clays; nor is it a thing too often to be repeated on any ſoil, eſpecially where the ſoil is ſhallow; nor muſt corn be ſown too long on ſuch lands. It is moſt proper for thoſe lands that have lain long untilled, and have contracted a ſour juice, which cauſes it to run to unprofitable trumpery, as ſour graſs, quitch, ruſhes, heath, gors (furze), fern, broom, &c. and land that runs too much to ſtraw, and yields but a lank ſhort ear, is much improved by burning.

Whether this operation be right upon the whole has been a ſubject of much diſpute, which I preſume not to determine. According to Mr. Kirwan it reduces the roots of vegetables to coal and aſhes, and thus prepares both a ſtimulant and nutriment for plants. It is commonly objected to the practice that it diminiſhes and conſumes the ſoil, repeated experience however has ſhown the contrary, at leaſt where the operation is judiciouſly managed[c].

Mr. Young relates that Colonel St. Leger has practiſed paring and burning for ſeveral years in Yorkſhire; and that he alſo breaks up old turf in that manner, however thin the ſoil may be. He pares it as thin as poſſible, becauſe the roots make the good aſhes, not the earth. He is clear that it does not diminiſh the ſoil, for on various lime-ſtone lands, where the ſoil is not four inches thick, paring and burning has been regularly practiſed for ſeveral ages; and had it been attended by ſuch an effect, the whole ſtaple of the ſoil muſt long ſince have totally diſappeared: whereas he has conſtantly found that with good management it enſures very great crops. The farmers indeed generally take four or five crops of corn after it, and with the laſt ſow any vile rubbiſh called hay-ſeeds: many do not ſow any thing, but leave the ſoil to turf itſelf. Then it lies for a ſheep-walk twenty or twenty-one years, and then they pare and burn again with the ſame ſyſtem.

To condemn paring and burning from ſuch miſmanagement, is to argue againſt the uſe of a good thing from the abuſe, which is a mode of reaſoning by no means uncommon. Or if we ſhould allow the poſſibility of paring and burning being hurtful to the ſoil, yet the evils ariſing from the miſmanagement of common farmers are by no means to be received as proofs of ſuch ſuppoſed prejudice: they are effects of bad huſbandry, not of paring and burning.

Colonel St. Leger recommends the pared and burnt land always to be ſown with turneps; to be kept in tillage ſeven years, in a good courſe of crops; and then to be laid down again to graſs, with plenty of good ſeeds; and ſoon after to be well manured[d].

Skirting and *beat-burning* have been practiſed ſeveral centuries in Cornwall and Devonſhire: and whether it is intended to ſow wheat or turneps, this is the uniform mode of breaking up graſs lands. *Skirting* is a ſort of half ploughing; as two or three inches of ſurface of the ley is left untumed, and is covered by the furrow, cut very thin, with the graſſy ſide downwards; ſo that the graſs ſide of the furrow, and the narrow balk which is left untumed, being in contact, ſoon rot by the fermentation of the ſward. If for turneps it is turned thin about midſummer, and is immediately worked: if to lay to rot for wheat, in the fall of the year it is turned a little deeper. The operation is performed by a wing turned up the furrow ſide of the plough-ſhare, which cuts the furrow any breadth that is choſen, generally about four inches and a half. This operation is ſometimes performed by ſpading, or paring with a breaſt-plough; ſometimes alſo with a mattock: but ſkirting with the plough is generally practiſed. The beſt time for this operation is before Chriſtmas, if the graſs can be ſpared: the winter froſts bring it into fine order, but in general it is done in ſummer. After laying ſome time, it is croſs-cut with the plough and well worked with harrows, and then either left to rot, or again harrowed and rolled with much care and labour, until the broken ſward is made very light, and the earth ſhaken from the graſſy roots and weeds, which are then raked together by hand into heaps and burnt; which proceſs is called *beat burning*[e].

Whatever ill effects paring and burning may produce in bad hands, and with ſuch great miſchief has certainly been done, where a ſyſtem of corn crops is the object in view; there is no doubt of its expediency in ſituations that are elevated or remote from markets, where the great object of the cultivator ought to be to get the land as quickly as poſſible into good paſture. Where the ſurface is covered with very coarſe herbage or heath, reſt-harrow, fern, &c. or if the ſoil conſiſts of moſs to a conſiderable depth, this operation is very properly employed to deſtroy the rubbiſh, and render the land workable. It may then be reduced by fallow, and ſown with graſs and white clover, either with or without a crop. Lime harrowed in with the graſs ſeeds, will much increaſe the richneſs and ſweetneſs of the paſture. But a ſeries of white crops will exhauſt the land, and ſhould always be guarded againſt by the landlord, where paring and burning is practiſed.

FOLDING

Is reſorted to by all open-field farmers as the preparation for wheat, and their chief dependence is upon this ſpecies of top-dreſſing, where the quantity of farm-yard dung is inſufficient for their purpoſe. This mode of manuring is peculiarly adapted to farms where there is a conſiderable extent of hill or common paſture, or graſs lands that never come under the plough. In ſuch farms, by bringing the ſheep in the evening to the fold, a conſiderable quantity of manure will be made, that would otherwiſe be loſt. If the paſture upon which the ſheep feed through the day be good, they may be fulded without much detriment to the animal for a great part of the year; but where the paſture is ſcanty this cannot well be done, for the ſheep will not be able to pick up a ſufficiency of food

through the day to enable them to bear the fatigue of travelling to and from the fold, and fasting all night. And unless the sheep have turneps or hay during the winter, their dung will be of small value.

It is a bad practice to crowd more sheep into a fold than can lie down at their ease, and it is equally bad to confine young and old, strong and weak in the same fold. It is far better to afford them room enough, and to let them remain on the same spot two or three nights till it is sufficiently manured.

Feeding sheep in a fold can only be practised upon light dry soils. Here it is still more necessary neither to crowd the flock, nor to put in the weak with the strong; for they will tread down and waste the food, and in the contention for it the strong will deprive the weak of their proper share.

On light dry soils sheep will do good by giving it cohesion with much treading; but on clays or strong loams this does much injury to the land; turneps, &c. cannot therefore be fed off in such soils, except in dry seasons, but must be pulled and eaten upon a dry stubble or pasture.

Upon farms entirely arable, where artificial grasses make a part of the rotation, to bring the flock from the pasture, to fold it upon a fallow, is only enriching one part of the farm at the expense of another[1]. Or, as Mr. Bakewell always called folding, *robbing Peter to pay Paul*. It is well known that heaths and sheep-walks that have been fed time out of mind, but the sheep constantly folded on other lands, continue as miserably poor as they ever were at any former period.

But besides this, lambs and ewes are damaged by folding, to the amount probably of at least 1s. a head. Now the benefit arising from their dung is estimated at about 1s. 2d. a head; which leaves only 6d. each for the advantage of this practice. But there is still another deduction to be made on the number kept and loffes on ſtock. Divide one thouſand ſheep into ten flocks of one hundred each, by means of inclo-ſures, and twelve hundred would be kept eaſier than a thouſand were before; and as to many of the diſtem-pers and accidents to which flocks are liable, ſome of which are contagious, they reſult very much from this practice of folding[2].

If folding be ſuppoſed neceſſary on account of the manure, where farm-yard dung is not made in a ſuf-ficient quantity, and other manure is not readily to be obtained; might not a greater ſtock of muck be raiſed, by littering a dry part of the yard, or a warm corner of ſome paſture with ſtraw, fern, or whatever litter could be had in greateſt plenty, penning them and feeding them there in hard weather, and letting them run into the adjoining paſture only during the day in fine weather. A great quantity of manure might thus be raiſed in winter from a flock, and pro-vided they had ample room in the pen, and were to be well ſupplied with dry litter, the ſheep might ſuſ-tain leſs injury in thus lying warm and dry, than from being folded on naked land, often wet, and in an open expoſure.

If indeed we expect other good effects on land be-ſides the dung and urine of the ſheep, as their tread-ing, and a certain warmth communicated to the ſoil by their breath, their perſpiration, and the natural heat of their bodies, then folding may be adviſeable.

WATER.

May fairly be conſidered as a manure, if we attend to the effects of ſtagnant and putrid water, and the watering of meadow lands.

Water, if allowed to remain ſtagnant is diſpoſed to putrefy, from the animal or vegetable matters con-tained in it; and when it has undergone a putrefac-tion, it depoſits a mucilaginous ſubſtance. Water therefore may be rendered an excellent manure, by making a pond or reſervoir near a houſe and farm-yard the common receptacle of the drains from the kitchen, ſcullery, and waſh-houſe, or of the yard, ſtables, &c. or elſe by throwing into it weeds and all offal of the garden. By either of theſe means there may always be a large ſupply of putrid water, with which, particularly in dry ſeaſons, meadow and paſture land may be watered with great effect, by means of water-carts, ſuch as are uſed on the roads near London[3].

The water in which flax or hemp is ſteeped might be uſed advantageouſly in the ſame manner; and in general, where there are any pits or pools, the water might ſoon be rendered putrid and fit for manuring paſture or even arable lands, by throwing into them a large quantity of green vegetable ſubſtances. In Devonſhire it is a practice to enrich ponds by the drain of an adjoining yard, with the addition of a bag of lime at different times.

Watering of meadows is a moſt important improve-ment, where it can be accompliſhed, and is well un-derſtood. A well-watered meadow is in ſpring a hot-bed for graſs. The practice of this valuable improve-ment may be learnt from Mr. Davis's Agricultural Survey of Wiltſhire, copied in the article MEADOW.

This, together with Fallowing, Draining, &c. is in ſome degree connected with the preſent ſubject as im-provements of land, but not being properly manures, are here omitted.

The baſis of the preceding diſſertation on Manures is the outlines of the propoſed general Report from the Board of Agriculture on the ſubject of Manures, together with the Appendix. To this is added a va-riety of practical information from Dr. Hunter's Geor-gical Eſſays, Mr. Arthur Young's Annals of Agricul-ture, Mr. Marſhall's Rural Economy of Norfolk, the Midland Counties, &c. The Papers of the Bath Agricultural Society. The Surveys of Counties printed by direction of the Board of Agriculture, &c.

SPECIES.

1. Mappia guianenſis.
   Soramia guianenſis. *Aubl. guian.* 552. *t.* 219.

DESCRIPTION, *&c.*

This is a ſhrub, with branches full of little tuber-cles, rambling over trees, to their very tops, and di-viding into many alternate branchlets, which are long and hang down. Upon theſe are leaves, which are alternate, ſmooth, thick, narrowing at the bale, where they terminate in a petiole, an inch in length, thick, convex underneath and channelled above: the largeſt are ſix inches long, and three inches and a half wide: they are divided by a longitudinal nerve, prominent beneath, with ſeveral lateral nerves ſpringing from it. Flowers in little bunches from the axils of the leaves, or on the tubercles of the branches and branchlets. Pedunckles long, reddiſh, ſlender. Calyx alſo reddiſh within. Corolla white. Berry red, the ſize of a

DESCRIPTIONS, *&c.*

The generic of natural character of Maranta is given differently from Schreber's as above, by Swartz in his obſervations.

CAL. *Perianth* three-leaved, ſuperior. *Leaflets* lanceolate, longer than the tube of the corolla, contiguous.

COR. one-petalled, ringent. *Tube* cylindric, compreſſed, oblique, gibbous. *Border* trifid. *Segments* equal, lanceolate ovate; one loweſt, two lateral.

NECT. *Nectary* three-parted, connate with the tube: two lower diviſions oblong, lateral, larger, repreſenting a lower lip: the third upper larger, vaulted, ſerving for a filament.

STAM. *Filament* none. *Anther* linear, faſtened to the upper edge of one of the ſegments of the nectary.

The reſt as before, except that the ſtyle is crooked in the middle.]

1. This has a thick, fleſhy, creeping root which is very full of knots, from which ariſe many ſmooth leaves, ſix or ſeven inches long, and three broad towards their baſe, leſſening towards each end, terminating in points. They are of the conſiſtence and colour of thoſe of the Reed, and ſtand upon reed-like foot-ſtalks, which ariſe immediately from the root, between theſe come out the ſtalks, which riſe near two feet high; theſe divide upward into two or three ſmaller, and have at each joint one leaf of the ſame ſhape with the lower, but ſmaller. The ends of the ſtalks are terminated by a looſe bunch of ſmall white flowers, ſtanding upon pedunckes near two inches long. The flowers are cut into ſix narrow ſegments, which are indented on their edges; theſe ſit upon the embryo, which afterwards turns to a roundiſh three-cornered capſule, incloſing one hard rough ſeed. It flowers here in june and july.

[Browne ſays that it grows from a thick fleſhy root, and ſhoots by a ſimple foliated ſtalk to the height of two or three feet, terminating in a looſe and ſomewhat branched flower-ſpike. It is called Indian Arrow-root, becauſe it was thought to extract the poiſon from wounds inflicted by the poiſoned arrows of the Indians.

It is conſidered in the Weſt Indies as a warm alexipharmic, and is thought to reſiſt the force of poiſons very powerfully; but its chief effects ſeem to depend on its abſorbent and lenient nature, having few warm particles in its compoſition.

The root waſhed, pounded fine and bleached, makes a fine powder and ſtarch. It has been ſometimes uſed as food when other proviſions were ſcarce, and is frequently adminiſtered in infuſions to the ſick [a]. The flower in milk is recommended as a proper food for infants, and is gelatinous like Salep. It has lately been introduced into England.

It is a native of South America, and is cultivated in the Weſt Indies.] It was firſt diſcovered by Plumier. Dr. Houſtoun found it in great plenty near La Vera Cruz, and ſent the ſeeds to England [before 1732.]

2. Miller ſays, this is very like the firſt, but has a ſingle ſtalk: the flowers are ſmaller, and the ſegments of the petals are entire.

This plant, not agreeing in character with Maranta, as deſcribed by Linnæus, Loureiro removed it into the genus Amomum; where it is alſo placed in this work. Swartz ſuggeſted that it is an Alpinia, and Willdenow has placed it in that genus. See the deſcription, &c. under Amomum.

3. Culm round, ſolid, very regular, ſhining, without knots at bottom, divided at top into ſpreading branches, eight feet high. Root creeping, horizontal, tubercled, woody. Leaves broad-ovate, ſubacuminate, quite entire, alternate, obliquely ſtriated. Petioles round, ſlender, lengthy. Flowers white, ſubterminating, in large, ſcattered, nodding panicles [b].

Native of the Eaſt Indies, Cochinchina, the Iſland of Cayenne and Guiana; where it is uſed for making baſkets [c].

It ſeems doubtful whether it belongs properly to this genus.

4. This is a doubtful plant. Coſtus malaccenſis, deſcribed by Koenig, in Retz. faſc. 3. 71. ſeems to be allied to it.

5. Leaves radical, petioled, even, like thoſe of Canna. Scape leafleſs, round, even, the thickneſs of a ſwan's quill, three feet high. Coma terminating: leaflets cluſtered, numerous, ſeſſile, ovate, reflex; the lower gradually ſmaller. Flowers among the lower leaflets of the coma, ſeſſile, each with bifarious bractes,

* Aublet.

[a] Browne jam. [b] Loureiro. [c] Aublet.

in

in three pairs: the upper valves two-keeled, the lower equal. Florets in threes. Perianth caducous; leaflets petaloid, the length of the corolla: the tube of which is almoſt the length of the calyx; the border five-parted, four ſegments lanceolate, the fifth biſid. Filament ſhort, placed on the tube. Anther erect, oblong. Germ ſhort. Style filiform, club-ſhaped, faſtened to the tube below. Stigma narrow, ſimple. Seeds very many.

Native of Surinam, where it was found by Dalberg. Perhaps it may conſtitute a new genus; the appearance is certainly very different from that of the others*.

Aublet has ſeveral other ſpecies of Maranta, but his deſcriptions of them are too ſhort to enable us to form any judgment concerning them. Probably ſome do not belong to this genus.]

PROPAGATION AND CULTURE.

Theſe plants being natives of a warm country, are very tender, and therefore will not live in this climate, unleſs they are preſerved in ſtoves. They may be propagated by their creeping roots, which ſhould be parted in the middle of march, juſt before they begin to puſh out new leaves. Theſe roots ſhould be planted in pots filled with light rich earth, and plunged into a moderate hot-bed of tanners bark, obſerving now and then to refreſh them with water; but it muſt not be given to them in large quantities, for too much moiſture will ſoon rot the roots, when they are in an unactive ſtate. When the green leaves appear above ground, the plants will require more frequently to be watered, and they ſhould have free air admitted to them every day, in proportion to the warmth of the ſeaſon, and the heat of the bed in which they are placed. As the plants advance in ſtrength, they ſhould have a greater ſhare of air, but they muſt conſtantly remain in the ſtove plunged in the tan, otherwiſe they will not thrive; for when the pots are placed on ſhelves in the ſtove, the moiſture paſſes too ſoon from the fibres, which generally ſpread on the ſides and bottoms of the pots, ſo that the plants do not receive much nouriſhment from the water. But where they are conſtantly kept in the tanners bark, and have proper air and moiſture, they will thrive, ſo as from a ſmall root to fill the pot in which they were planted, in one ſummer. About michaelmas the firſt ſort will begin to decay, and in a ſhort time after the leaves will die to the ground, but the pots muſt be continued all the winter in the bark-bed, otherwiſe the roots will periſh; for although they are in an inactive ſtate, yet they will not keep very long from ſhrinking, when taken out of the ground; and if the pots are taken out of the tan, and placed in any dry part of the ſtove, the roots often ſhrivel and decay; but when they are continued in the tan-bed they ſhould have but little water given to them when their leaves are decayed, leſt it rot them. The firſt ſort flowers conſtantly in july or auguſt, and will often produce ripe ſeeds in England, but the ſecond ſort does not flower ſo conſtant, nor do the flowers appear ſo conſpicuous, being very ſmall and of a ſhort duration. This ſort never has produced any ſeeds in England, nor could I ever obſerve any rudiment of a ſeed-veſſel ſucceeding the flower. The green leaves abide on this ſort moſt part of the winter, ſeldom decaying till february; and ſometimes will continue green until freſh leaves come up, and thruſt the old ones off.

[MARASAKKI. See *Baſella*.

MARATTIA. (*So named by Swartz, in honour of Giovanni Francesco Maratti, an Italian Botaniſt, author of ſeveral treatiſes on cryptogamous plants, and eſpecially of the exiſtence of flowers in Ferns.*)

Lin. gen. Schreb. n. 1623. *Swartz prodr.* 128. *Smith ic. ined.* 2. 46, 47, 48. Myriotheca. *Juſſ.* 15. (excluſo Cænopteride Bergii).

Claſſ. 24. 2. Cryptogamia Filices.

Nat. order of *Filices* or *Ferns*.

ESSENTIAL CHARACTER.

Capſules oval, gaping longitudinally at top, with ſeveral cells on each ſide.

* Linn. ſuppl.

SPECIES.

1. Marattia alata.

Swartz. prodr. 128. *Smith ic. ined.* 2. 46.

Rachiſes ſcaly, the partial ones winged, leaflets ſharply ſerrate.

2. Marattia levis.

Smith ic. ined. 2. 47.

Rachiſes even, the partial ones winged; leaflets bluntly ſerrate at top, the uppermoſt confluent.

3. Marattia ſraxinea.

Smith ic. ined. 2. 48.

Rachiſes even ſimple; leaflets lanceolate ſerrate all diſtinct.

DESCRIPTIONS, &c.

1. Frond bipinnate, with the pinnas generally oppoſite. Rachis almoſt four-cornered: ſcales ſcattered, lineal, acute, membranaceous, duſky. Partial rachiſes with more frequent ſcales: wings narrow, the ſame ſubſtance with the leaflets, but veinleſs and quite entire, contracted and evaneſcent at the inſertion of the leaflets. Pinnules generally oppoſite, ſeſſile, ovate-lanceolate, acutely ſerrate, eſpecially towards the top, veined, the veinlets almoſt always biſid near the outſide, ending in the tips of the ſerratures, ſometimes, like the central nerve, minutely ſcaly. The lower pinnules are lobed, the upper ones entire: the terminating one elongated, acuminate, ſerrate-lobed. Capſules ſolitary, placed on the partial veins beyond the middle, before they open roundiſh or oval, the ſize of Poppy ſeeds, even, with a longitudinal cleft above, which afterwards gapes, and diſcovers a double row of little holes, about five on each ſide, communicating with the cells of the capſule. Finally the rim of the capſule becomes cloven and ſublobed.

Native of Jamaica, where this Fern has been remarked by Roger Shakeſpear, Everard Home, and Olaus Swartz.

2. Frond ſubtripinnate, with the lower pinnas alternate. Rachis roundiſh. Partial rachiſes flatted, winged above: wings the ſubſtance of the leaflets, veinleſs, quite entire, contracted at the inſertion of the leaflets, towards the top of the pinna much wider than in M. alata. Pinnules alternate, very ſeldom oppoſite, lanceolate, ſmooth, ſerrate-lobed, moſt frequently alſo pinnate at the baſe, ſerrate at the tip, ſerratures ſomewhat bent in, blunt not acuminate, veined; veins ſmooth, uſually ſimple except in the partial leaflets; the upper ones oval, bluntly ſerrate not lobed: the end one elongated, acute, bluntly ſerrate, lobed at the baſe, with the lobes confluent in the uppermoſt pinnules. Capſules uſually ſolitary, often two on a lobe of the pinnules, each placed on its proper vein, roundiſh or oval, little more than half the ſize of the preceding, even, opening longitudinally, with four (ſeldom five) little holes on each ſide, the rim always entire, never cloven or lobed.

Native of St. Domingo, where it was found by Thierry.

3. This is a very large Fern, with a handſome leaf like that of the Aſh. Frond unequally bipinnate, with the pinnas alternate. Rachis half-round, channelled, ſmooth; partial rachis with little or no membranous wing towards the top. Pinnules alternate, ſcarcely petioled, lanceolate, acuminate, ſerrate, even, uniform, gradually ſmaller towards the baſe of the pinna. Partial veins numerous, ſimple and divided alternately, ſpreading, ending in the tips of the ſerratures. Capſules towards the edges of the pinnules, ſolitary, placed on the veins, before they open oval, the ſize of the ſeeds of Lepidium ſativum, even; when theſe ſplit open longitudinally about ſix little holes appear on each ſide.

Native of the iſland of Mauritius. Thouin†.

MARCGRAVIA. (*From George Marcgraaf of Liebſtadt in Germany. Author of a voyage to Braſil in* 1648.)

Lin. gen. n. 640. *Reich. n.* 696. *Schreb. n.* 871. *Plum.* 29. *Jacqu. amer.* 159. *Juſſ.* 244.

† Smith.

GENERIC CHARACTER.

Cal. *Perianth* six-leaved, imbricate, permanent: *leaflets* roundish, concave: the two outmoſt larger.

Cor. one-petalled, come-ovate, entire, cloſed like a calyptre, parting at the baſe, caducous.

Stam. *Filaments* very many, awl-ſhaped, ſhort, ſpreading, deciduous. *Anthers* upright, large, ovate-oblong.

Pist. *Germ* ovate. *Style* none. *Stigma* headed, permanent.

Per. *Berry* coriaceous, globular, many-celled, many-valved.

Seeds numerous, ſmall, oblong, neſtling in ſoft pulp.

ESSENTIAL CHARACTER.

Cor. one-petalled, calyptre-ſhaped. *Cal.* ſix-leaved, imbricate. *Berry* many-celled, many-ſeeded.

SPECIES.

1. Maregravia umbellata.

Lin. ſpec. 719. *ſyſt.* 487. *Reich.* 2. 562. *Swartz obſ.* 205. *Jacqu. amer.* 156. *t.* 96. *pict.* 77. *t.* 143. *Plum. gen.* 7. *ic.* 173. *Brown. jam.* 244. *t.* 26. (opt.) *Sloan. jam.* 1. 74. *t.* 28. *f.* 1. (Phillitidi affinis.)

DESCRIPTION, &c.

This is a ſtrubby creeping plant, but not properly paraſitical, at firſt it is radicant, like ſome Ferns, whence Sloane has given a figure of a young plant among his Ferns. As it advances the ſtem becomes ſhrubby, adhering ſtill by its fibres to the trunk of ſome tree, to the top of which it frequently runs, at length dividing into ſeveral ſubdivided looſe pendulous branches, commonly terminated by flowering umbels. The leaves of a young rooting plant are roundiſh, ſubſeſſile, ſlightly emarginate, with an entire margin, and glandular dots. Leaves of the branches diſtich, alternate, on ſhort petioles, ovate, lanceolate or ovate-lanceolate, of a thick conſiſtence, deciduous, ſmooth. Umbels rodding, with many, ſimple, one-flowered pedunicles. In the centre of the umbel utricular glands, ſpreading, oblong, ventricoſe, helmet-ſhaped, deciduous, corneous[1]. Flowers aſcending naked. Receptacle, after the flower is fallen, entire not five-lobed[2]. Capſule uſually divided into ten cells. Seeds and pulp of a ſhining ſcarlet colour[3].

Native of the Weſt Indies, in the cool woody mountains. Browne ſays it is frequent in the woods of Jamaica, and appears in ſuch various forms that it has been miſtaken for different plants in the different ſtages of its growth.

MARCHANTIA. (*So named in honour of Nicholas Marchant, M. D.*)

Lin. gen. n. 1198. *Reich. n.* 1315. *Schreb. n.* 1661. *March. act. gall.* 1713. *t.* 5. *Mich.* 1. *Juſſ.* 9. *Schmid. ic.* 9. 29. 31. 34. *Hedw. theor.* 96. *t.* 24, 25. Hepatica. *Mich.* 2. Lunularia. *Mic.* 4. Lichen. *Dill. muſc.* 515.

Claſſ. 24. 4. Cryptogamia Hepaticæ.

Nat. order of *Algæ. Hepaticæ*, Juſſ.

ESSENTIAL CHARACTER.

Male. *Calyx* ſalver-ſhaped: *anthers* numerous, imbedded in its diſk.

Fem. *Calyx* pelate, flowering on the under ſide. *Capſules* opening at top, *ſeeds* faſtened to elaſtic fibres.

Seven ſpecies of Marchantia are received in Syſtema Vegetabilium. Of theſe five are natives of Britain. M. polymorpha is very common in wet places; as on ſhady walls, and by the ſides of wells and ſprings. In figure it ſomewhat reſembles an oak leaf. The pedunicles are in the angles of the lobes, from one to three inches high. Capſules greeniſh, dividing into eight or ten ſegments. On the upper ſurface are here and there glaſs-ſhaped conical cups, on ſhort pedicels, with a wide fealloped margin, and incloſing about four little bodies, very finely ſerrated at the edges[4].

Mr. John Lindſay, ſurgeon in Jamaica, ſowed that part of the fructification of this Alga, compoſed of fine elaſtic filaments and ſmall globules, heretofore conſidered as the male parts, where none of the plants had ever been ſeen before: and in a ſhort time raiſed ſeveral young *Marchantiæ*, which grew freely.

The *Marchantia* bearing ſeeds of another kind in ſmall ſeſſile cups, which alſo readily grow, may have the appearance of ſuperfluity. But may not theſe be conſidered as in ſome ſort analagous to thoſe luxuriant productions in many vegetables, hence called viviparous; as in the Graſſes, the genus Allium, &c.

Mare's-Tail. See *Hippuris*.

MARGARITARIA. (*From* Margarita, *a pearl, the kernels of the berries being of a ſhining white, like pearls.*)

Lin. gen. Schreb. n. 1533. *Suppl.* 66. *Juſſ.* 430.

Claſſ. 22. 7. Dioecia Octandria.

GENERIC CHARACTER.

* *Male.*

Cal. *Perianth* one-leafed, four-toothed, minute, permanent.

Cor. *Petals* four, roundiſh, inſerted into the calyx.

Stam. *Filaments* eight, briſtle-ſhaped, patulous, longer, inſerted into the receptacle. *Anthers* roundiſh, ſmall.

Pist. *Germ* ſuperior, roundiſh. *Style* briſtle-ſhaped, the length of the ſtamens. *Stigma* blunt.

* *Female*, on a diſtinct individual.

Cal. as in the male, permanent.

Cor. as in the male?

Pist. *Germ* ſuperior, globular. *Styles* four or five, filiform. *Stigmas* ſimple, permanent.

Per. *Berry* globular, crowned with ſhort patulous ſtyles.

Seed. *Aril* four or five-grained, four or five-celled, cartilaginous, very thining; with two-valved lobes. *Seeds* ovate, compreſſed inwards.

Obs. *Calyx always four-cleft. Styles and Arils four or five.*

ESSENTIAL CHARACTER.

Male. *Cal.* four-toothed. *Cor.* four-petalled.

Fem. *Cal.* and *Cor.* as in the male. *Styles* four or five. *Berry* cartilaginous, four or five-grained.

SPECIES.

1. Margaritaria nobilis.

Lin. ſyſt. 890. *ſuppl.* 428. *Pluk. phyt. t.* 176. *f.* 4.

DESCRIPTION, &c.

In the male the branches are round, brachiate, flexuoſe. Leaves oppoſite, petioled, ovate, even, quite entire, of a firmer conſiſtence, the ſize of Euonymus leaves. Panicle of compound racemes, with great abundance of ſmall flowers, as in Spiraea Aruncus. Germ blunt, minute, abortive, with a ſimple ſtyle.

In the female the branches are alternate. Leaves always alternate. Pedunicles axillary, ſimple, always one-flowered. Calyx always flat, four-cleft. Styles four or five, ſpreading above the germ, permanent. Berry globular, but the nucleus four or five-grained, ſhining remarkably and the colour of pearls.—Perhaps theſe may be of different genera?

Found in Surinam by Dalberg[1].

Marque. See *Rhizophora*.

MARICA.

Lin. gen. Schreb. n. 81. Cipura. *Aubl. t.* 13. *Juſſ.* 58.

Claſſ. 3. 1. Triandria Monogynia.

Nat. order of *Enſatæ. Irides*, Juſſ.

GENERIC CHARACTER.

Cal. *Spathes* bivalve.

Cor. ſix-parted. *Petals* three outer ovate, three inner ſmaller; all connate at the claws.

Stam. *Filaments* three, very ſhort, inſerted into the tube of the corolla. *Anthers* oblong, erect.

Pist. *Germ* inferior, angular. *Style* three-cornered. *Stigmas* three, petal-form, ſimple, acute.

Per. *Capſule* oblong, angular, three-celled.

Seeds ſeveral, angular.

ESSENTIAL CHARACTER.

Cor. ſix-parted, with three alternate ſegments as ſmall again as the others. *Stigma* petal-form, triſid, with the three diviſions ſimple, acute. *Capſ.* three-celled, interior.

SPECIES.

1. Marica paludoſa.

Lin. ſpec. Willd. 246.

Cipura paludoſa. *Aubl. guian.* 1. 38. *t.* 13.

[1] Swartz. [2] Linn. ſpec. [3] Jacquin. [4] Weis, Pollich, Wilkening.

[1] Linn. tranſ. 2. 313. [2] Linn. ſuppl.

DESCRIPTION, &c.

Root a fleshy bulb, covered with several membranes as in Saffron. Leaves from the bulb four or five, surrounding and covering it with their bases, more than a foot long, narrow, pointed, thin, striated. Stem stout, with two leaves at the top, and some others that are shorter; from the middle of these issue several flowers, each inclosed in a membranous spathe. The three intermediate segments of the corolla hollowed like a spoon, are very small: the colour is white or blue. Style and stigmas blue.

Native of the moist meadows of Guiana, at the foot of the mountain Courou: flowering in auguſt*.

MARIGOLD. See *Caltha*.

MARILA. (*Marila, ashes or embers.*)

Lin. gen. Schreb. n. 1756. *Swartz prodr.* 84.

Claſs. 13. 1. Polyandria Monogynia.

GENERIC CHARACTER.

CAL. *Perianth* five-leaved: *leaflets* oblong, blunt, ſpreading.

COR. *Petals* five, obovate, waved at the edge, ſpreading, longer than the calyx.

STAM. *Filaments* very numerous, inſerted into the receptacle, a little connate at the baſe, filiform; the inner ones the ſame length with the corolla, the outer gradually ſhorter. *Anthers* ovate.

PIST. *Germ* linear, four-cornered, ſuperior. *Style* ſhort, thick. *Stigma* blunt, ſubcapitate.

PER. *Capſule* ſubcolumnar, incurved, four-cornered, four-celled, four-valved.

SEEDS very numerous, like ſaw-duſt, ciliate.

ESSENTIAL CHARACTER.

Cal. five-leaved. *Cor.* five-petalled. *Capſ.* four-celled, many-ſeeded. *Stigma* ſimple.

SPECIES.

1. Marila racemoſa.
Swartz prodr. 84.
Native of the Weſt Indies; at Montſerrat and St. Chriſtopher's.]

Borders of the calyxes flat villoſe, leaves cordate concave, ſemi-brushy.

11. Marrubium acetabuloſum. *Saucer-leaved White Horehound.*
Lin. ſpec. 817. *fiſt.* 538. *Reich.* 3. 67. *Barr. ic.* 129. (Dictamnus).

Pſeudo-dictamnus acetabulis molliceps. *Baub. pin.* 222.—*alter* Theophraſti, Pona. *Park. theat.* 28. *f.* 3. *Raii hiſt.* 558.

Borders of the calyxes longer than the tube membranaceous, the greater angles rounded.

DESCRIPTIONS, *&c.*

1. Root biennial. Stems about the ſame height with the common ſort. Leaves hoary, bluntly toothed. Whorls of flowers ſmall and looſe. Segments of the calyx end in very ſtiff prickles, ſpreading open. Flowers dark purple, larger than thoſe of the common ſort.

[Linnæus remarks, that there are three ſmall purple flowers on each ſide: and that the calyxes are acute with the teeth ſpreading.

Native of Spain and Italy. Cultivated by Gerarde before 1597. It flowers in july and auguſt [a].

Vahl ſays, that M. ylleatum of Forſkahl ſcarcely differs from this: but it agrees in its rigid ſtalk, plaited leaves agminated into the petiole at the baſe, unequally and bluntly toothed, in the want of an involucre, and its rigid pungent calyxes: it differs however in having ten-flowered whorls, which yet is often the caſe in M. Alyſſon, and the whole plant is woolly white, with the leaves leſs wedge-ſhaped and rounder.]

2. Stems near three feet high, branching much more than the common ſort. Leaves rounder, whiter, and ſtanding farther aſunder. Whorls of flowers not ſo large: but the corolla has a longer tube.

[Like the next ſpecies, there are ſeveral ſtems from the ſame root, procumbent at the lower part, but riſing upright above, ſomewhat longer and more ſlender than in that: leaves narrower, not ſo thick, villoſe or wrinkled, but ſofter, with a more delicate down, and more hoary: the flowers, eſpecially the helmet, are divided into ſharper ſegments: the calyxes are more deeply ſtreaked, and are cut into longer ſegments, more ſtanding out [b].

Native of the Levant, Auſtria, Sicily, &c.].

β. Thin riſes with ſlender hoary ſtems near three feet high: the leaves are very hoary, much longer and narrower than thoſe of the preceding: the whorls of flowers are ſmaller, and the briſtly indentures of the calyx longer and erect: the whole plant has an agreeable flavour.

[Native of Tabanin. *Lin.* Miller ſays Spain and Portugal. There were cultivated in the Eltham garden before 1732.

Dillenius remarks, that M. album latifolium and anguſtifolium of Caſpar Bauhin are upright plants, taller and ſtouter, and more branched; that the latter has a ſtrong ſmell, and has ſharper leaves; but that the former is inodorous, like his plant, with a bitter taſte, which he has not: the leaves of the broad-leaved variety are more narrowed at both ends, more bluntly and not ſo frequently crenate: finally that the leaves of his plant are ſofter and whiter.]

[a] Hort. kew. [b] Dillenius.

3. This has ſtalks about the ſame length as thoſe of the common ſort. [They are from a foot to a foot and half in height, procumbent at the lower part, but riſing upright at top, obtuſely quadrangular and villoſe. Leaves thick, much wrinkled and villoſe, pale green and hoary, the upper ones ſmaller. Flowers at the end of the ſtem and branches in cloſe whorls, white, the upper lip erect and bent back, blunter than in the other ſorts; the lower lip three-parted, the middle ſegment entire, blunter and ſomewhat wider than the lateral ones. Calyxes villoſe, divided into five ſharp ſegments, almoſt equal, the three upper ones ſomewhat ſhorter; they are ſeſſile, and are ſurrounded by an involucre of many capillaceous leaves [a].

There is ſome confuſion here, and according to Retzius, the plant with ovate-lanceolate ſhining ſilky leaves, ſerrate from the middle to the tip, but entire in the other half, and the teeth of the calyx awl ſhaped is M. hiſpanicum ſiliquum fol. ſericeis argenteis, figured by Dillenius in *t.* 174. *f.* 215. See the preceding ſpecies.

Native of the Levant. (Miller ſays Spain). Cultivated in 1732, by James Sherard, M. D. It flowers from july to ſeptember [b].

4. Stems ſeveral, perennial, half a foot high, branched and procumbent, from which annually ſpring many other ſtems, which are herbaceous, erect, a foot long, ſparingly branched, woolly-villoſe and hoary. Leaves petioled, hoary, wrinkled very much, tomentoſe on both ſides, ſoft, ovate, blunt, ſerrate, bitter, having ſcarcely any ſmell; the younger ones that come out with ſtems extremely woolly. Whorls very cloſe compoſed of very many ſeſſile flowers, with an involucre of awl-ſhaped acute woolly leaflets. Perianth tubular, hoary, very woolly at the edges, rigid: the five toothlets lanceolate-acuminate and erect. Corolla twice as long as the calyx: tube cylindrical, white: border purple: upper lip linear, cloven as far as the middle, erect, villoſe at the back: lower lip trifid, the length of the upper: the lateral ſegments ſhorter, oblong and blunt; the middle one very large, broad and roundiſh, emarginate, flat, ſtretching forward. Filaments very ſhort concealed within the upper part of the tube. Anthers roundiſh, duſky. Style the length of the ſtamens [c].

Native of Aſtrachan. It flowers in may.]

5. Stems ſeldom above eight or nine inches long, covered with a ſoft hoary down. Leaves ſmall, roundiſh, very ſoft to the touch, hoary, indented on the edges. Whorls of flowers ſmall, very downy, and white.

[Scopoli places that ſynonym of Dillenius which has been given under *M. peregrinum*, and which Retzius ſuſpects to belong to *M. candidiſſimum*, under his ſiliquum. He ſays that *M. album* anguſtifolio of John Bauhin differs only in having the leaves ſerrate and ſharp, and the flowers ſmall: and that his plant not being ſiliquoſe, is intermediate between the ſecond ſpecies and this.

Native of Spain and the South of Europe. Cultivated in 1714, in the botanic garden at Cheſea. It flowers from auguſt to october [d].

6. Root perennial. The whole plant white with down. Stems upright, a foot or eighteen inches in height, branching towards the top. Lower leaves roundiſh, upper ſomewhat ovate; all wrinkled, with thick veins beneath, bluntly ſerrated about the tip, an inch wide, and as long or longer, running down into the petiole, which is half an inch long and channelled above. Whorls very cloſe, conſiſting of above forty, ſome above fifty ſeſſile flowers. Calyx woolly, fringed on the inſide at the bottom of the teeth with woolly hairs; having as many ſtreaks on the outſide as there are teeth, which are uſually ten, but ſometimes twelve, the teeth are whitiſh, recurved, alternately larger and ſmaller. Corolla ſmall, white, compreſſed, ſtriveling in the calyx; tube curved a little; upper lip lanceolate or linear, blunt, deeply cloven; the lower has the middle ſegment bent back and ſlightly ſcalloped, the lateral ſegments lanceolate, entire, ſhort-

[a] Ibid. [b] Hort. kew. [c] Jacquin. [d] Hort. kew.

The two shorter filaments, according to Scopoli, are villose at top, but the two longer ones smooth. Anthers yellow, with a black substance in the middle. The involucre under the whorls is bristle-shaped [s].

Common White Horehound has a strong penetrating smell, not altogether unpleasant. It was a favourite medicine with the ancients in obstructions of the viscera. In large doses it loosens the belly. It is a principal ingredient in the negro Cæsar's remedy for vegetable poisons. A young man, who had occasion to take mercurial medicines, was thrown into a salivation which continued more than a year. Every method that was tried to remove it, rather increased the complaint. At length Linnæus prescribed an infusion of this plant, and the patient got well in a short time. No quadrupeds seem to eat it [h]. Bees much frequent the flowers.

Native of most parts of Europe, by road sides and in waste places, flowering from june to september.

7. Root perennial. Stem two feet high, upright, subtomentose, deeply grooved on the opposite sides. Branches opposite. Leaves wrinkled, subtomentose. Whorls remote. Involucres many-leaved, linear, ciliate, nearly the length of the calyxes. Calyx tubular, curved, hispid, nine or ten-streaked, nine or ten-toothed; toothlets short, awl-shaped, the uppermost longer, spinulose. Corolla white, smaller than the calyx: upper lip villose on both sides, slightly bifid; lower three-parted; the lateral segments semiovate, entire, diverging: the middle reflex, truncated, slightly two-nicked: tube long, linear. Filaments the length of the tube: anthers yellow, with shining dots, visible only in the microscope [i].

Retzius remarks that this plant has the involucre of Phlomis, the corolla of this genus, and the anthers of Leonurus; informuch that he is doubtful to what genus it ought to be remarked: but he had an opportunity of observing only one plant, and that in an imperfect state.

Linnæus distinguishes this from the next species, which it resembles, by the helmet or upper lip of the corolla being emarginate and hairy.

Native of the Cape of Good Hope. Introduced in 1774, by Mr. Francis Maſſon. It flowers from july to september [k].

8. Stem suffruticose, upright, rough-haired. Leaves petioled, very much wrinkled, crenate, subtomentose, hairy underneath. Calyx funnel-form, ten-toothed. Corolla purple, not hairy: upper lip roundish, blunt, entire; lower trifid, with the middle segment bifid, the sides ones stretched out. Anthers not beyond the throat or opening. It is a different plant from that which is figured by Hermann *t.* 200, that having the upper lip lanceolate and bearded, and the flamens the length of the lip.

Native of Italy, Sicily, and Spain [l].

Miller has two species, crispum and suffruticosum (n. 8 and 9.) The first of these, he says sends out many stiff roundish stalks, more than two feet high, covered with a white cottony down. The tube of the corolla is scarcely so long as the calyx, so that the two lips are but just visible.

The second has shrubby stalks near three feet high, dividing into small branches; the leaves are heart-shaped; the tube of the corolla is longer, and the flowers are larger; they are of a pale purple colour, and the upper lip is erect.

The leaves of both are rough on their upper side, and woolly on their under; the whorls of flowers are large, and the borders of the calyx flat and hairy.

9. The stalks of this grow more erect than those of the common sort; the leaves are rounder and more serrate; the calyx spreads open, and the segments are acute; the flowers are like those of the common sort; the whole plant is very hoary.

[According to Linnæus, the leaves are roundish, flat and crenate; the upper lip of the corolla trifid or quadrifid; the teeth of the calyx alternately larger and smaller.

[s] Withering, Woodw. Mis. Pollich. Scop. Krocker. Rav.
[h] Withering. Linn. suec. [i] Retzius. [k] Hort. kew.
[l] Linn.

Native of Spain. Cultivated in 1759 by Mr. Miller. It flowers in july and auguſt [m]. Mr. Miller affirms that he had the seeds from Istria.]

10. This rises with a shrubby stalk two feet high, and dividing into many branches. Leaves small, sitting pretty close to the stalks. The whorls of flowers not so large as those of the eighth sort. The rim of the calyx flat. The flowers white. The whole plant very hoary with a dense compact cotton.

[Native of the island of Candia; Miller says Sicily and the islands of the Archipelago.—Cultivated by Gerarde in 1596. It flowers from june to auguſt [n].]

11. Stems hairy, about two feet high. Leaves heart-shaped, rough on their upper side, and hoary on their under, deeply serrate. Whorls large. Border of the calyx flat; segments many, membranaceous, angular, and rounded at the top. Corolla small, pale purple, scarcely appearing out of the calyx: upper lip erect.

[The teeth of the calyx are acuminate. After flowering time the border of the calyx grows out till it becomes twice as long as the tube, and is naked and membranaceous, not villose as in the preceding species: the margin of the border has twenty angles; the smaller ones acute, the broader ones very blunt and rounded [o].

Native of the island of Candia. Cultivated in 1731 by Mr. Miller. It flowers from june to auguſt [p].]

PROPAGATION AND CULTURE.

All these plants are preserved in botanic gardens for the sake of variety, but there are not above two of the sorts which are cultivated in other gardens; these are the tenth and eleventh sorts, whose stalks are shrubby: the plants are very hairy, and make a variety when intermixed with other plants; these very rarely produce seeds in England, so are propagated by cuttings, which, if planted in a shady border the middle of april, will take root pretty freely.

They are somewhat tender, and in very severe winters are killed, unless they are screened from the hard frosts, especially those plants which grow in good ground, where becoming luxuriant in summer, their branches are more replete with juice, and very liable to suffer by cold; but when they are in a poor dry rubbish, the roots being short, firm, and dry, are seldom injured by cold, and will continue much longer than those in better ground.

The other sorts are easily propagated by seeds, which should be sown on a bed of poor earth in the spring, and when the plants come up they must be kept clear from weeds; and where they are too close they should be thinned, leaving them a foot and half asunder, that their branches may have room to spread; after this they require no other culture; they may also be propagated by cuttings, in the same manner as the other two sorts. If these plants are upon a dry poor soil, they will live several years, but in rich land they seldom last above three or four.

MARSILEA. (*So named by Linnæus, in honour of Count Aloysius Ferdinando Marsigli of Bologna, founder of the Institute there, author of the history of the Danube, and several other works, between* 1681 *and* 1726.)

Lin. gen. n. 1618. Lemma. *Juss. gen.* 16. *act. gall.* 1740. 263. *t.* 15 Salvinia. *Mich. gen. t.* 58. Class. 24. 1. *Cryptogamia Miscellaneæ.*

GENERIC CHARACTER.

Cal. *Common* oval, subcompressed, coriaceous, hairy, gaping at the base, internally divided into several (fourteen or fifteen) cells, in two longitudinal rows, separated by a membranaceous partition.

Cor. none.

Stam. *Filaments* none. *Anthers* several, inserted round each pistil, very small, obovate, sharp below, one-celled, gaping transversely, exploding a spherical pollen.

Pist. in each cell several, coadunate in a transverse row, oval. *Style* none. *Stigma* short, blunt.

Per. none.

Seeds as many as there are pistils.

Rec. *Membrane* somewhat fleshy, clothing the cells internally.

Obs. *Calyxes one, two, or three, pedicelled issue from the petiole of the leaf a little above the rest.*

Leaves in fours toothletted.

INSCRIPTIONS, *&c.*

Michell first gave this respectable name to plants which prove only to be species of Jungermannia. To the first of the above plants, Michell had given the name of Salvinia, from Ant. Maria Salvini, a noble Florentine, professor of Greek, but not of Botany. The elder Jussieu and Necker both separate the second species from Linnæus's genus of Marsilea.

1. Branches floating. Leaves in two rows, ovate, folded together, having little balls scattered over them, composed of four white filaments, cirrhose at the tip; among the roots globes from three to seven, furnished with a style, many-seeded [a].

Native of Italy, in stagnant and slow-flowing marsh ditches, as near Pisa; also in North America.

2. Capsules toothless [b]. Stem creeping, rooting. Leaves on long petioles, flowering at the base of the petiole. Involucre pedicelled, ovate, transversely many-celled; cells having pistils and anthers placed on the same receptacle promiscuously [c].

Native of France, Alsace, Siberia, India, in ditches.

3. This is very like the preceding, but differs in having a smaller and more rigid stem; the whole plant is less; the leaves are toothlet-crenulated, and seven times smaller; the capsules are two-toothed at the base, even, compressed.

Native of the East Indies.

β. Seems to be only a very minute variety, though most of the leaves are in a manner quite entire; some of them however are crenulate [d].

Marsilea. See *Isoetes* and *Jungermannia*.]

Martagon. See *Lilium*.

MARTYNIA. (*So named by Houstoun, in honour of John Martyn, F. R. S. Professor of Botany at Cambridge, author of* Historia Plantarum rariorum, *and many other works, editor of* Virgil's Georgicks and Eclogues. *Born sept.* 1699, *died jan.* 1768.)

Shrubby, leaves lanceolate-serrate toothed, upper lip of the corolla with numerous curled segments.

DESCRIPTIONS, &c.

[These are annual plants, except the first and last. Stem herbaceous, except the last. Leaves simple, mostly opposite, but sometimes alternate. Flowers in axillary and terminating short spikes or bunches. Calyx five-leaved in the first and third, five-cleft in the rest. Corolla specious, blue, red or white variegated with elegant dots and lines. Distinct from the Personatæ, and approaching to Pentandria in having a fifth imperfect stamen: in the third species two of the principal stamens are imperfect. Germ inferior in the first and last. Fruit more than two-celled, commonly four-celled, some with a long, others with a short beak.]

1. Root perennial, thick, fleshy, divided into scaly knots, somewhat like those of Toothwort. Stems annual, about a foot high, thick, succulent, purplish. Leaves oblong, thick, sessile, rough and of a dark green on their upper side, but purplish underneath. The stem is terminated by a short spike of blue bell-shaped flowers, not spreading open so much at the rim as in the third sort.

[Linnæus observes, that the fruit appears to be inferior; hence Jussieu would refer it with the last species to Gesneria.]

It was discovered by Mr. Robert Millar, growing naturally about Carthagena in New Spain, whence he sent the seeds to Europe.

[2. Stem upright, somewhat rugged, two feet high. Leaves opposite, petioled, three-nerved. Flowers axillary, solitary, on short peduncles. Instead of stipules at the base of each peduncle, a gland or little cup with a ball in it, having as it were a short style and stigma. Perianth very small, five-toothed. Tube of the corolla very long, more contracted in the middle, gibbous on the dorsal base. Germ superior. Style the length of the tube. Stigmas linear, two, revolute. Pericarp scarcely beaked, having a thick toothlet on each side at the base. Seeds small.]

Native of the Cape of Good Hope. Introduced in 1781, by the Countess of Strathmore *.

3. This is a handsome large plant, two feet high, straight, with large leaves, viscid from small slender simple white villose hairs, each of which has a pellucid clammy globule at the top,

Stem single, round, reddish green. Branches several, brachiate, dichotomous. Root-leaves none. Stem-leaves opposite, angular, with teeth remote by a long finis, flaccid, green, white from the closeness of the villose hairs, veined, the largest six inches long; petioles on the stem horizontal, on the branches spreading, the same length with the leaf. Flowers several, on short peduncles, hanging down, so that the throat is turned towards the ground, disposed in a thyrse in the forks of the branches, two inches and a half long. Bractæ double, one anterior two lines below the calyx, two-leaved, sessile; leaflets ovate, blunt, dry, villose only at the edge, easily deciduous, reddish green: the other one-leafed, very large, opposite to the end of the peduncle, on a sort of winged petiole, ovate-orbicular, angular, nerved, dry, with the upper edge bent in, falling off before the flower expands. Perianth five-leaved; three of the leaflets lanceolate, slender, one-nerved, two ovate, thicker, three-nerved, yellowish green, the whole deciduous. Corolla inferior, five times the length of the calyx: tube white tinged with purple, and spotted red and yellow: border pale red, with a shining purple spot on each segment, two-lipped; upper lip reflex, bifid; lower straight, trifid, the middle segment longer, wider, with a yellow spot at the base resembling a bifid stigma supported on a style. Filaments straight, inserted into the anterior part of the corolla, and applied to it, thickish, the length of the tube: two larger at the sides, sterile; two smaller in the middle without anthers, and between these the rudiment of a fifth. Anthers oblong, two-celled. Germ superior, contracted in the middle. Style thickish, flat, shorter than the filaments. Stigma two-plated, plates flat, placed one against the other, gradually becoming more and more remote; after fecundation it shrivels and gapes. * Under a green shell, shining with clamminess, coriaceous, juiceless, acuminate at both ends, is concealed the capsule, an inch long, black, woody, very hard, ovate, compressed, four-grooved. Seeds four, one in each cell, oblong, compressed, black, with a white pith or pulp.]

Miller says, that the corolla is shaped like that of the Fox-glove, but of a paler purple colour: that the capsule is thick, tough and clammy, when ripe dividing into two parts, and leaving a large hard nut hanging on the plant, about the size and shape of the same forms the flat-beetle, with two strong crooked horns at the end; it has two deep longitudinal furrows on the sides, and several smaller crossing each other in the middle; it is so hard, that it is with difficulty cut open without injuring the seeds; within it are four oblong cells, two of which have generally a single oblong seed in each, but the other two are abortive. The flowers at the divisions of the branches may be brought forward in July, those at the extremities come afterwards, so that there is a succession of flowers on the same plant to October, when the plants decay.

It was discovered by Dr. William Houstoun, near La Vera Cruz, in New Spain, whence he sent the seeds to England, which succeeded very well in the botanic garden at Chelsea; and in the year 1731, several of these plants were raised, which produced their beautiful flowers, and perfected their seed, whence several plants were raised the succeeding year.

[This has been much confounded with the fifth sort.

4. See the description, &c. under *Craniolaria*. It is now generally agreed that these genera ought to be united: both having a monopetalous ringent corolla, with the rudiment of a fifth stamen; and a capsule similar in structure.

5. This is a large plant, two feet high, flexuose, herbaceous, villose, viscid. Stem single, round, pale green. Branches several, scattered, resembling the stem. Root-leaves none. Stem-leaves opposite and alternate, sessile, waved, veined, yellowish green, five inches long. Petioles horizontal, slightly channelled above, the length of the leaf. Flowers several, pedunculed, in a loose thyrse in the forks of the branches, two inches long. Bractes two at the base of the calyx, lanceolate-ovate, front yellow green, red-veined, thrivelling, deciduous. Perianth inflated, the three upper segments lanceolate, acute, the lower lobed, deciduous. Corolla inferior, four times as long as the calyx: tube yellowish white, variegated with green, yellow and violet spots; border wide, waved, pale violet, with saffron-coloured and violet dots and lines, divided into two less distinct lips; segments roundish, the middle one larger, painted at the base with sulphur-coloured lines resembling the filaments and the style with the stigma. Filaments thickish, white with violet dots, inserted into the bottom of the tube, the smaller winding round the larger, the same length with the tube. Anthers two-celled; cells ovate, converging. There is a rudiment of a fifth stamen. Germ oblong-acuminate. Style roundish, white, the length of the stamens. Stigma two-plated; plates roundish, crenate, it gapes, but closes with a touch. Under a coriaceous, green, viscid, juiceless shell, acuminate both ways and two-valved, is concealed the capsule, a hard long, swelling, woody, blackish, obsoletely quadrangular, with many excavations, crested along the back, and having a very

* Gent.

long

long hooked beak; it opens by two valves, and is incompletely five-celled. Seeds subcordate, compreſſed, rugged[a]. Gærtner adds, that there are four cells, but that a fifth ariſes, when the tranſverſe partitions becoming ripe recede from each other, and leave an empty ſpace in the axis of the fruit: partitions coriaceous, riſing thick from the lateral grooves, but extenuated into tranſverſe laminas, and oppoſite to each other. Seeds about twelve in the whole capſule, ovate-acuminate, berried, when ripe rugged with tubercles, black with a coppery brightneſs; they are in a ſingle longitudinal row in each cell, and faſtened to the partitions. The fruit is ſo well figured by this author, as that of the third ſpecies is by Houſtoun, that they cannot be miſtaken. The whole plant of the third is alſo figured by Martyn and Ehret; as that of the fifth is by Miller, Gloxin, Sabbati, Kretzchmar and Schmidel, ſo well that there can be no difficulty in diſtinguiſhing them.—The Proboſcidea may alſo be known by its ſcattered branches, leaves oppoſite and alternate, cordate-ovate, quite entire, waved and ſomewhat rigid; its one-leafed calyx; the tube of the corolla very wide, with the border more irregular; all the four filaments fertile, and bent in one among another; and finally by the very long beaks to the capſule[b].

Native of America. Cultivated in 1759 by Mr. Miller. It flowers from june to auguſt[c].

6. See the deſcription under Geſneria, to which genus it certainly belongs from its habit, inflorescence, flower and fruit. Linnæus's generic character by no means accords with it, and Plumier was long ſince aware of its affinity to Geſneria[d].

It may be added, that the ſtem is upright; the leaves ſolitary and villoſe; the flowers ſolitary from the angles of the branches; calyx permanent, ſegments long and ſharp[e].

Cultivated by Mr. Miller in 1759.]

PROPAGATION AND CULTURE.

1. The firſt ſort dies to the root every winter, and riſes again the ſucceeding ſpring; this muſt be conſtantly preſerved in the ſtove, and plunged into the bark-bed, otherwiſe it will not thrive in this country. During the winter ſeaſon, when the plants are decayed, they ſhould have but little water given to them, for at that time it will rot the roots. In the middle of march, juſt before the plants begin to ſhoot, is the proper ſeaſon to tranſplant and part the roots, when they ſhould be planted into pots of a middle ſize, filled with light rich earth, and then plunged into the bark-bed, which ſhould at this time be renewed with ſome freſh tan. When the plants come up, they muſt be frequently refreſhed with water, but it muſt not be given to them in large quantities, leſt it rot their tender roots; and as the warmth of the ſeaſon increaſes, it will be proper to admit a large ſhare of freſh air, which will greatly ſtrengthen the plants; they muſt alſo be placed in the tan-bed, where they are not over-hung, or ſhaded by other plants, nor ſhould they be ſhifted or tranſplanted when they are in leaf, for that will prevent their flowering. As the roots of this plant increaſe very faſt, there is no neceſſity for uſing other methods to propagate it; otherwiſe the ſhoots of the young ſtalks will take root, if planted in pots filled with light earth, and plunged into a hot-bed during any of the ſummer months.

2. to 5. The annual ſorts muſt be propagated by ſeeds ſown in pots filled with light rich earth, and plunged into a hot-bed of tanner's bark, where if the earth be duly watered, the plants will appear in three weeks or a month; tranſplant them in a little time after they come up, each into a ſeparate pot, and plunge them into the hot-bed again, watering them well, and ſhading them until they have taken new root; after which they ſhould have a large ſhare of freſh air admitted to them in warm weather, by raiſing the glaſſes of the hot-bed every day: with this management the plants will make great progreſs, ſo as to fill the pots with their roots in about a month or ſix weeks time, when they ſhould be ſhifted into pots about a foot diameter at the top, filled with light rich earth, and then plunged into the hot-bed in the bark-ſtove, where they ſhould be allowed room, becauſe they put out many ſide branches, and will grow three feet high or more, according to the warmth of the bed, and the care which is taken to ſupply them conſtantly with water; and ſhould be conſtantly kept in the tan-bed, giving them plenty of free air at all times when the weather is warm, but they will not bear to be expoſed abroad in this country; when theſe plants thrive well they will ſend out many ſide branches, which will all of them produce ſmall ſpikes of flowers; but it is only from the firſt ſpike of flowers that good ſeeds can be expected in this country, ſo that particular care ſhould be taken, that none of theſe are pulled off or deſtroyed, becauſe it is very difficult to obtain good ſeeds here; and I believe few of thoſe that are produced on the ſide branches in the natural country of their growth, are fully ripened; for I have received a great quantity of theſe ſeeds from abroad, which have appeared to be very good, and yet few of them have grown.

The ſeeds of theſe plants have a ſtrong green covering on them, as thick as the outer covering of an Almond, and when the ſeeds are ripe, the covering opens, and lets the ſeeds fall, in the ſame manner as the covering of Almonds, Walnuts, &c. In each covering there is one hard nut, in ſhape ſomewhat like a beetle, having two ſharp crooked horns at one end. This nut contains four embryos, but there are ſeldom more than two ſeeds which are perfect in any of them. However, when they are ſown, the whole nut muſt be planted, for it is ſo hard, that it is almoſt impoſſible to take out the ſeeds without ſpoiling them; and when there are two plants produced from the ſame nut, they are eaſily ſeparated, eſpecially if they are tranſplanted while young. Theſe ſeeds will continue good for ſome years, for I ſaved a pretty large quantity of them in the year 1734, part of which I ſowed the following year, but had not one plant produced from them; the remainder of the ſeeds I divided, and ſowed ſome of them every ſucceeding year, without any ſucceſs, until the year 1738, when I ſowed all the ſeeds I had left, from which I had one plant produced; ſo that if the ſeeds are good, it is evident they will grow when they are four years old; therefore, whenever we receive good ſeeds from abroad, or have any in this country which are perfectly ripened, it will be proper to preſerve ſome of them for a year or two, leſt a bad ſeaſon ſhould happen, when the plants may not perfect their ſeeds; ſo that if this precaution be not taken, the ſpecies may be loſt in Europe.

5. This is more hardy than the third ſort, ſo that the plants may have more air; and too much water in ſummer will rot the ſucculent ſtems before the ſeeds are perfected.

5. Matricaria canonicensis.
Linn. ecobinch. 498. ed. Willd. 609.
Leaves leaves ferrate, uppermoſt quite entire, pedunckes one-flowered, floretts of the ray entire, receptacle convex.

DESCRIPTION, &c.

Theſe are herbaceous plants, with leaves moſtly pinnate, but in ſome few caſes ſimple (n. 6. 7.). Flowers terminating, either in corymbs, or almoſt ſolitary. Florets in the ray commonly white, ſeldom abortive; in M. Afteroides numerous and linear. This has the ſeed five-toothed at top*; and is not properly a Matricaria.

The plants of this genus, Cotula and Anthemis, are hardly to be diſtinguiſhed by the habit. But this is a difficulty frequent in Natural Orders.

1. Common Feverfew has a perennial or biennial root, compoſed of a great number of fibres, and ſpreading wide on every ſide. Stem from two to three feet high, erect, firm, round, ſtriated, ſlightly hairy, branched on every ſide. Leaves petioled, alternate, pale green, ſoft and tender, pinnadid with two or three pairs of ovate jagged pinnas, and a larger one terminating, three-lobed, wedge-ſhaped, the middle lobe trifid, the ſide-lobes notched, roughiſh, ſlightly hairy: when magnified they appear as if ſprinkled with minute ſpangles. Flowering heads ſolitary, ſometimes on ſimple, but oftener on branched peduncles, forming together a looſe umbel or rather corymb, hairy; the peduncles are thickeſt juſt beneath the flower, and about two inches long. Scales of the calyx numerous, ovate, with dry membranaceous margins, which is one character of *Chryſanthemum*. Florets of the ray wedge-ſhaped, terminated by three teeth, and white; thoſe of the diſk crooked, ſprinkled with minute ſhining particles, yellow only at the top. Sometimes the florets of the ray are wanting; and the flowers frequently become double. Seeds whitiſh, with deep longitudinal furrows, ovate, truncated at the baſe. Receptacle dotted*.

Native of many parts of Europe, in waſte places, under hedges and walls, in church-yards, ſometimes in corn-fields, in gardens, where it is alſo cultivated in a double ſtate.]

Miller enumerates ſeven varieties—

1. With very double flowers.
2. With double flowers, having the florets of the ray plane, as of the diſk fiſtular.
3. With very ſmall rays.
4. With very ſhort fiſtular florets.
5. With naked heads, having no rays.
6. With naked ſulphur-coloured heads.
7. With elegant curled leaves.

They flower in june, and the ſeeds ripen in auguſt.

[The whole plant has a ſtrong ſmell, to moſt perſons unpleaſant, and a bitter taſte. It yields an eſſential oil by diſtillation. It has always been eſteemed a good emmenagogue, whence its name *Parthenium* (Dioſcorides, Theophraſtus, &c.) and Matricaria. It is alſo ſerviceable in hyſteric complaints. The beſt way of taking it is in a ſlight infuſion. It is an agreeable carminative and bitter, ſtrengthening the ſtomach and diſperſing flatulencies. The expreſſed juice is ſaid to kill worms in the bowels. It has likewiſe been recommended as a febrifuge, whence its Engliſh name Feverfew.

In German it is *Mutterkraut, Mutterkamille, Jungferenkraut, Mutternenkraut, Muter, Mater, Mutrich, Mutterwurz, Mahlerkraut, Magdblum, Fieberkraut.* In Dutch, *Mauwel, Mater, Moederkruid.* In Daniſh, *Moderurt.* In Swediſh, *Mattrom.* In French, *Matricaire, Espargoutte.* In Italian, *Matricaria, Matricali, Matrica.* In Spaniſh and Portugueze, *Matricaria.* In Ruſſian, *Matafchonaja trawa.*]

2. The ſtalks of this plant branch out pretty much, and ſpread near the ground. Leaves dark green, like thoſe of the true Chamomile (Anthemis nobilis), but much thicker in ſubſtance; their edges are turned back. Flowers white, like thoſe of the true Chamomile, and diſpoſed almoſt in form of an umbel.

* Juſſieu. † Wood. Mſs. Withering.

[Root woody, running deep, apparently perennial. Stems reclining, about nine inches long, thickiſh purple, ſmooth, firmer and ſtronger than thoſe of Anthemis nobilis; the whole plant is ſtouter, grows more by tufts, and does not ſpread ſo wide or creep ſo much. Leaves thicker and ſhorter, ſhining, dark green. Flowers ſeveral on a ſtem. Florets in the ray white, entire, in the diſk yellow. In ſmell it approaches to the true Chamomile, but is is much weaker †.

Krocker takes it to be a biennial plant. According to him, the ſtems are eighteen inches long; the peduncles are grooved and one-flowered; the flowers large; the receptacle hemiſpherical or conical; the florets of the ray three-toothed; the calycine ſcales ſurrounded with a brown membranaceous margin; the ſeeds of the ray three-toothed and triangular.

Retzius remarks, that in the garden it becomes perennial and luxuriant, with an upright ſtem more than two feet high, and leaves four times larger than in the wild plant, inſomuch that it appears to be a different ſpecies.

Native of the coaſt of Britain. Dillenius firſt obſerved it in Suſſex, about Cockbuſh, ſeven miles from Chicheſter. Afterwards Mr. Atkinſon remarked it in Iſle of Walney, Dr. Smith on the rocks at Down near Bamff in Scotland, and Mr. Lightfoot in the Iſle of Bute, and on the weſtern ſide of Cantire between Machrianiſh and Barr, &c. It flowers in july. Krocker aſſigns it alſo to Sileſia, on the banks of the Oder, the borders of fields, and dunghills; but I doubt whether his plant be the ſame with ours.

3. Hudſon and Withering will have this to be no more than a variety of the next ſpecies; and Lightfoot could perceive no difference between them, except that the rays of this are larger and deflexed.

According to Krocker the ſtem is ſmaller, leſs divided, few-flowered, ſmooth, weaker, higher. Leaves longer, ſofter, with linear, bifid pinnules. Flowers a little larger; the florets of the ray narrower, bent down. The receptacle conical, whitiſh. The ſcent ſweet and pleaſant, but leſs penetrating than that of M. Chamomilla or Anthemis nobilis.

Gærtner deſcribes the receptacle as ovate-conical, acuminate, high, raiſed-dotted, naked. Seeds ſmall, inverſely pyramidal, grooved, ſmooth, whitiſh, bald.

He remarks that the receptacle in the other ſpecies is much ſhorter and merely convex; and that if the ſeeds of Matricaria had a crown, the genus would be changed into that of *Pyrethrum*.

Native of Siberia, Germany, Sweden, and Britain: flowering from may to auguſt.

Its properties reſemble thoſe of Anthemis nobilis. The Finlanders uſe an infuſion of it in conſumptive caſes. Cows, goats and ſheep eat it. Horſes are not fond of it. Swine refuſe it ‡.

4. Root annual. Stem green, ſtriated, ſmooth, branched. Leaves deep green, alternate, ſeſſile; the lower ones doubly pinnate, pinnas diſtant, pinnulas bifid or trifid; the upper ones often ſimply pinnate, pinnas linear, and of an equal breadth with the midrib. Flowering heads ſolitary, on long, upright, ſtriated, naked peduncles, a little thickened above, terminating the ſtem and branches. Scales of the calyx bluntly lanceolate, with a green dorſal line, hairy, with membranaceous edges. Florets of the ray about thirteen, white, almoſt linear, a line and half broad, two-grooved, three-toothed, teeth bluntiſh; they are at firſt ſpreading, afterwards reflex. Mr. Curtis remarks, that they begin to hang down in the evening, and continue to do ſo till morning, both in this and Anthemis Cotula. Florets of the diſk yellowiſh green. Seeds numerous, minute, pale brown, furrowed; the furrows deeper and more numerous on the inner ſide, the ridges white §.

Corn Feverfew is common on cultivated grounds, on dunghills, and by way ſides; flowering from may to auguſt, and even to october. Several plants are confounded with this, under the common names of

† Dillen. in Ray ſyn. ‡ Withering.
§ Woodw. Mſs. Curtis, Stokes in Withe.

Mayweed, Maithes, Dog-Finkle, or *Dog-Fennel.* It differs from *Anthemis Cotula* or Stinking Mayweed, which it most resembles, by its scent, in having a higher and larger stem, the leaves of a darker green, and cut into finer segments. The heads of flowers smaller, smell somewhat like the true Chamomile, only not so pleasant: but those of Stinking Mayweed are very disagreeable, and the plant will blister the skin on being much handled. The florets of the ray in *Matricaria* are in general longer and much narrower; the disk is more prominent and of a darker yellow than in *Anthemis*; which the botanist readily distinguishes, on dissecting it by the pointed chaffs fixed to the receptacle, between the florets, and which are totally wanting in *Matricaria*. The seeds of *Anthemis* are broad and truncated at top, wrinkled, and of a deep brown colour; those of *Matricaria* are much smaller, paler, and different in shape. These distinctions are the more necessary to be attended to, because these plants are extremely similar in their general appearance, are often found growing together, both are annuals flowering at the same time, and both grow nearly to the same height [1].

Mr. Curtis joins Hudson and Lightfoot in affirming that M. suaveolens is not different from this; and is surprised that Professor Murray should adopt a species founded on such vague characters. See however what is said above from Krocker and Gaertner.

According to the Swedish observations, kine, goats and sheep eat this plant, horses are not fond of it, and swine refuse it. It seems to be rejected by quadrupeds in general with us. It is supposed to possess the same qualities with the officinal Chamomile (Anthemis nobilis), but in an inferior degree.]

5. This rises a foot high. Leaves of a silver colour, for the most part placed opposite. The peduncles arise single from the side of the branches, each supporting one white flower.

Native of the Levant. It flowers in July, and in warm seasons seeds are sometimes perfected in autumn.

6. For the description see Bolronia Asteroides.]

Miller describes his Matricaria americana to be a perennial plant, with the stalks and leaves decaying in autumn. The former rise a foot and half high, and divide at top into several forked branches: at each of the divisions is placed one linear-lanceolate leaf, about two inches long, and a quarter of an inch broad, of a deep green. The branches are terminated by single peduncles, each supporting one blue flower, very like those of some Asters, but the calyx is scaly, and the seeds have not any down. It flowers in July and August, and the seeds ripen in autumn.

[7. Native of Curaçao [2].

8. Stems herbaceous, a foot and half high, cespitose, suberect, branched. Leaves lanceolate. Flowers terminating, solitary, on upright peduncles. Calycine leaflets acute. Florets of the disk yellow, five-cleft, short, almost closed: of the ray blue, quite entire. It has some affinity with M. Asteroides.

Native of China near Canton.]

PROPAGATION AND CULTURE.

1. Common Feverfew is frequently cultivated in the physic-gardens near London to supply the market. The varieties are preserved in botanic and some flower gardens. Some of them are pretty constant, if care be taken in saving the seeds: but where these are suffered to scatter, it is almost impossible to preserve the varieties without mixture.

The seeds should be sown in march upon a bed of light earth, and, when they are come up, they should be transplanted out into nursery-beds, at about eight inches asunder, where they may remain till the middle of may, when they may be taken up, with a ball of earth to their roots, and planted in the middle of large borders, where they will flower in july and august; and, if the autumn be favourable, will produce ripe seeds the same year. But it is not advisable to permit them to seed, which often weakens and decays the roots; therefore, when their flowers are past, you should cut down their stems, which will cause them to push out fresh heads, whereby the roots may be maintained.

When the different varieties of these plants are intermixed with other plants of the same growth, they make a handsome appearance during the season of flowering, which commonly continues a full month, or more. But as their roots seldom abide more than two, or at most three years, fresh plants would be raised from seeds to supply their places; for although they may be propagated by parting their roots either in spring or autumn, yet these seldom make so good plants as those obtained from seeds; but the second variety seldom produces any good seeds, therefore that must be propagated in this manner, or by planting cuttings in the spring or summer months, which will take root, and make good plants.

2. This is seldom cultivated except in botanic gardens. Sow the seeds in autumn, soon after they are ripe, or in the spring, upon a bed of common earth, in almost any situation: when the plants come up thin them where they are too close, and keep them clean from weeds.

[3. May be propagated in the same manner.

4. Is a weed too common among slovenly cultivators of arable land.]

5. Sow the seeds in april, on a bed of light earth, in a good exposure, and when the plants are of a proper size, remove them into the borders of the flower garden.

6. Sow the seeds in autumn, soon after they are ripe, in the full ground, and when the plants are fit to remove, if they are planted in the borders of the flower-garden they will continue some years without protection, and annually produce flowers and seeds.

[MATRICARIA. See *Achillea, Anthemis, Chrysanthemum, Cotula.*

MATTHIOLA. (*So named by Plumier, from Petre Andrea Matthiolus, the famous Botanist, and Commentator on Dioscorides.*)

Lin. gen. n. 1231. *Reich. n.* 258. *Schreb. n.* 328. *Plum.* 6. *Pent.* 4. 39. *Juss.* 206.

Class. 5. 1. Pentandria Monogynia.

Nat. order of *Rhœadeæ*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* cylindric, quite entire, erect, short, permanent.

COR. *Petal.* one, very long, from a slender tube ending gradually in an entire border, with a repand mouth.

STAM. *Filaments* five, awl-shaped, shorter than the corolla. *Anthers* simple.

PIST. *Germ* globular, inferior. *Style* filiform, the length of the corolla. *Stigma* thickish, blunt.

PER. *Drupe* globular, crowned with the calyx, one-celled.

SEEDS. *Nut* globular. *Nucleus* globular.

OBS. *This genus is obscure, and it is probably nothing more than a species of* Guettarda, *perhaps* G. speciosa.

ESSENTIAL CHARACTER.

Cal. entire. *Cor.* tubular, superior, undivided. *Drupe* with a globular nucleus.

SPECIES.

1. Matthiola scabra.

Lin. spec. 1661. *Jacq.* 218. *Reich.* 1. 490. *Plum. gen.* 36. *ic.* 173. *f.* 2.

Rategal arbor indiana. *Lamar. hist.* 67. *t.* 75?

DESCRIPTION, &c.

Leaves scattered, ovate, bracteæ pinnate. This tree rests on the authority of Plumier, and requires further enquiry before any thing can be determined concerning it. Modern authors think that it is a species of Guettarda, and Richard affirms that it is the same with Guettarda speciosa.—Native of America [3].

MATTUSCHKÆA. (*From Count Matuschka, author of* Flora Silesiaca, 1776. 77. *in German. He died in* 1779.)

GENERIC CHARACTER.

CAL. *Perianth* four-parted: *segments* ovate, acute, villose.

COR. one-petalled. *Tube* long. *Border* four-cleft.

STAM. *Filaments* four, almoſt equal, the length of the ſegments of the corolla. *Anthers* roundiſh.

PIST. *Germ* ſuperior, four-cleft. *Style* filiform. *Stigma* ſimple.

PER. none.

SEEDS two or four, very ſmall, naked.

ESSENTIAL CHARACTER.

Cal. four-parted, with linear leaflets. *Cor.* one-petalled, with a long tube and four-cleft border. *Germ* ſuperior, four-cleft. Seeds four, naked.

SPECIES.

1. Mauruſchkaea hirſuta.

Vahl ſymb. 3. 11.

Perama hirſuta. *Aubl. guian.* 54. *t.* 18.

DESCRIPTION, *&c.*

Stem filiform, erect, frequently quite ſimple, hirſute, as is the whole plant, eſpecially the calyx. Leaves almoſt like thoſe of Thymus Serpyllum, ſeſſile, oppoſite, acute, veinleſs, obſcurely three-nerved; the loweſt ſmaller, approximating, ovate: the upper oblong, remote, three lines long. Flowers in a terminating ſeſſile head, the ſize of a pea. This plant is a finger's length or a hand in height, or more, but never ſo gigantic as Aublet has drawn it, according to an obſervation of von Rohr, an eye-witneſs, who gathered it in Guiana, and communicated it to Lund[1].

MAUDLIN. See *Achillea*.

MAURA. See *Anthoxyze*.

MAURITIA. (*From the name Mauritii-Boom, by which it is known among the Dutch at Suriſaam.*)

Lin. gen. Schreb. n. 1702. *Suppl.* 70. *Juſſ.* 40.

App. Palmæ.

Nat. order of *Palmæ*.

GENERIC CHARACTER.

* *Male* flowers in an oblong ſeſſile *ament*, covered all round with flowers cloſely approximating; with *blunt ſcales* between the flowers.

CAL. *Perianth* one-leafed, cup-ſhaped, truncated, entire, three-fided, ſhort.

COR. one-petalled. *Tube* ſhort, the length of the calyx. *Border* three-parted: *ſegments* equal, ſpreading a little, lanceolate, rigid (in a manner woody) blunt.

STAM. *Filaments* ſix, inſerted into the throat of the tube, thick, very ſhort. *Anthers* linear, angular, the length of the ſegments of the corolla; three alternate ones extended between the ſegments of the corolla, and horizontal; the three others erect, preſſed cloſe to the channel of the ſegments.

* *Female*.

Unknown.

ESSENTIAL CHARACTER.

MALE in an oblong ſeſſile ament. *Cal.* one-leafed, cup-ſhaped, entire. *Cor.* one-petalled with a ſhort tube, and a three-parted border. *Filam.* ſix.

SPECIES.

1. Mauritia flexuoſa.

Lin. ſyſt. 1186. *Suppl.* 434.

DESCRIPTION, *&c.*

This is a ſingular tree, almoſt without leaves. Branches angular, flexuoſe, ſmooth, with ſhort joints, thickening upwards, ſomewhat recurved, terminated by embracing ſheaths; with a cup-ſhaped and ſharper knee-joint. From the axils of theſe come out over the whole ſtem ſtrobile-ſhaped aments, in two rows, ſpreading very much, ſeſſile, with two larger upright ſcales, ſickle-ſhaped upwards, at the baſe. Aments ovate-oblong, cylindric, covered with cloſely approximating, ferruginous flowers, ſpreading very much; falling off, and leaving the ament with its ſcales. The younger Linnæus laments that he was not acquainted with the female flowers or fruit.

Native of the woods of Suriſaam, where it was found by Dalberg[2].

His words are, "reſtituo Meadio "plantam, magis forte mercuri, quam plurimi alii, "quibus Sexuales conciſſere." Than which ſurely nothing is more true.]

MEADOW.

Under the general title of Meadow, is commonly comprehended all paſture land, or at leaſt all graſs land, which is mown for hay; but I chuſe rather to diſtinguiſh ſuch land only by this appellation, which is ſo low, as to be too moiſt for cattle to graze upon in winter, being generally too wet to admit heavy cattle, without poaching and ſpoiling the ſward; and thoſe graſs lands which are drier, I ſhall diſtinguiſh by the title of Paſture.

There are two ſorts of Meadows in England, one of which is ſtiled Water Meadows, and the other are ſimply called Meadows.

Water Meadows are thoſe which lie contiguous to rivers or brooks, from whence the water can be carried to overflow the graſs at pleaſure. Of theſe there are large tracts in ſeveral parts of England, which, if huſbandly managed, would become much more profitable to their owners than they are at preſent; for nothing can be more abſurd than the common practice of flowing theſe low grounds all the winter, whereby the roots of all the ſweeteſt kinds of graſs are deſtroyed, and only ſuch graſſes left as are natives of marſhes, which are coarſe and ſour: and if people were curious to examine the herbage of theſe water meadows, they would find the bulk of them compoſed of bad weeds, ſuch as grow by the ſides of rivers, brooks, and ditches, of which the ſeveral ſorts of docks make no ſmall ſhare; and although many of theſe meadows produce a great burden of what the country people call hay, yet this is only fit for cows, cart-horſes, and other animals, which by hard labour and hunger, are driven to eat it; for horſes which have been accuſtomed to feed on good hay, will ſtarve before they will touch it: and after the graſs is mown off theſe meadows, and cattle turned in to graze upon them, how common is it to ſee the land almoſt covered with theſe rank weeds, which the cattle never will eat! Which muſt always be the condition of ſuch meadows, where the water is let over them in autumn and winter; for the ſides of rivers and brooks every where abound with theſe rank weeds, whoſe ſeeds ripen in autumn, and falling into the water, they are carried by the ſtream, and depoſited on the flowed land, where they grow and fill the ground in every part; but ſo incurious are the generality of farmers in this reſpect, that if the ground is but well covered, they care not what it is, few of them ever taking any pains to weed or clean their paſtures.

The method which I propoſe for the management of theſe meadows is, never to flow them till the middle or latter end of march, excepting once or twice in winter, when there may happen floods, which may bring down a great ſhare of ſoil from the upper lands, at which times it will be of great ſervice to let water upon the meadows, that the ſoil may ſettle there; but the ſooner the wet is drained off when this is lodged, the greater advantage the meadows will receive by it; but from the end of march to the middle of may, in dry ſeaſons, by frequently letting on the water, the growth of the graſs will be greatly encouraged, and at this ſeaſon there will be no danger of deſtroying the roots of the graſs; and after the hay is carried off the ground, if the ſeaſon ſhould prove dry, it will be of great ſervice to the graſs, if the meadows are flowed again; but when this is practiſed, no cattle ſhould be turned into the meadows, till the ſurface of the ground is become firm enough to bear their weight without poaching

[1] Valt [2] Suppl.

poaching the land, for otherwiſe the graſs will ſuffer more from the treading of the cattle, than it will receive benefit by the flowing; but theſe are things which the country people ſeldom regard, ſo that the meadows are generally very unſightly, and rendered leſs profitable.

I would alſo recommend the weeding theſe meadows twice a year; the firſt time in april, and again in october; at which times if the roots of docks and all bad weeds are cut up with a ſpaddle, the meadows will ſoon be cleared of this trumpery, and the herbage greatly improved.

Another great improvement of theſe lands might be procured, by rolling them with a heavy roller in ſpring and autumn. This will preſs the ſurface of the ground even, whereby it may be mown much cloſer, and it will alſo ſweeten the graſs; and this piece of huſbandry is of more ſervice to paſtures than moſt people are aware of.

Watering of Meadows.

[The theory and practice of Irrigation Watering or Flowing Graſs Lands, being much better underſtood ſince the time of Miller, it will be proper to add here the beſt information that can be obtained on this important ſubject.

There being no part of the kingdom where the ſyſtem of watering meadows is ſo well underſtood, and carried to ſo great perfection as in Wiltſhire, the account of that practice as delivered by Mr. Thomas Davis, in his general view of the Agriculture of that county, drawn up for the Board of Agriculture, is here given.

Many of the moſt valuable and beſt formed Meadows were made at the beginning of this century. An imperfect ſcheme of watering had been practiſed before that period: but the regular mode in which this ſyſtem as connected with that of ſheep-folding is now conducted, is not more ancient. At preſent there is ſcarcely a river or brook in the diſtrict, that is not applied to this purpoſe.

It has been always obſerved that winter-floods produce fertility, provided the water does not remain too long on the land. But it is the taking off the water, and bringing it on again at will, that is the great buſineſs of irrigation, and thus making a water-meadow a hot-bed for graſs. The knowledge of the proper time and manner of doing this is the effect of obſervation.

Provided this great object can be accompliſhed, namely the bringing on and carrying off the water at pleaſure, it is not material what the ſhape of a water-meadow is, or that the diſpoſition of the trenches ſhould be uniform. But as very little land can be entirely commanded by water, unleſs its inequalities are reduced by manual labour,—it has been found convenient to adopt two different kinds of water meadows, one for land lying on declivities, and which muſt in general be watered from ſprings or ſmall brooks, and the other for low land near rivers, to be watered from thoſe rivers.

The firſt kind is called in Wiltſhire, "*catch work* "*meadows*," and the latter "*flowing meadows*." The latter are by far the moſt general in this diſtrict.

To elucidate the diſtinction between the two kinds of meadow, and to give ſome idea, what are the ſituations in which they may be introduced, it may be neceſſary to remark, that the "catch-work meadow" is made by cutting a ſpring, or ſmall ſtream, along the ſide of a hill, and thereby watering the land between the New Cut, (or as it is provincially called Main Carriage) and the original water-courſe which now becomes the "main drain." This is ſometimes done in particular inſtances, merely by making the new cut level, and ſtopping it at the end, ſo that when it is full, the water may run out at the ſide, and flood the land below it. But as the water would ſoon ceaſe to run *equally* for any great length, and would waſh the land out in gutters, it has been found neceſſary to cut ſmall parallel trenches or carriages, at diſtances of twenty or thirty feet, to catch the water again, and each of theſe being likewiſe ſtopt at its end, lets the water over its ſide, and diſtributes it until it is caught by the next, and ſo on over all the intermediate beds, to the *main drain* at the bottom of the meadow, which receives the water, and carries it on to water another meadow below, or, if it can be ſo contrived, another part of the ſame meadow on a lower level.

To draw the water out of theſe parallel trenches or carriages, and lay the intermediate beds dry, a narrow deep drain croſſes them at right angles, at about every nine or ten poles length, and leads from the main carriage at top, to the main drain at the bottom of the meadow.

When this meadow is to be watered, the ends of the carriages adjoining the croſs drains, are ſtopt with turf dug on the ſpot, and the water is thrown over as much of the meadow as it will *cover well* at a time, which the watermen call a "*Pitch of Work*;" and when it is neceſſary to lay this pitch dry, they take out the turves and let the water into the drains, and proceed to water another pitch.

This kind of water meadow is ſeldom expenſive: the ſtream of water being uſually ſmall and manageable, few *hatches* are neceſſary, and the land lying on a declivity, much leſs manual labour is required to throw the water over it regularly, and particularly *to get it off again*, than in the flowing meadows. The expenſe of making ſuch a meadow is uſually from three to five pounds per acre; the improvement frequently from fifteen ſhillings an acre to at leaſt forty. The annual expenſe of keeping up the works and watering the meadow, which is uſually done by the acre, ſeldom ſo high as 7*s.* 6*d.* per acre.

The other kind of water meadows, viz. thoſe uſually called "*Flowing Meadows*," require much more labour and ſyſtem in their formation. The land applicable to this purpoſe being frequently a flat moraſs, the firſt object to be conſidered is, how the water is to be *got off* when brought on; and in ſuch ſituations this can ſeldom be done, without throwing up the land in high ridges, with deep drains between them. A main carriage being then taken out of the river at a higher level, ſo as to command the tops of theſe ridges, the water is carried by ſmall trenches or carriages along the top of each ridge, and, by means of moveable ſtops of earth, is thrown over on *each* ſide, and received in the drains below, from whence it is collected into a main drain, and carried on to water other meadows, or other parts of the ſame meadow below. One tier of theſe ridges being uſually watered at once, is uſually called "a Pitch of Work;" and it is uſual to make the ridges thirty or forty feet wide, or, if water is abundant, perhaps ſixty feet, and nine or ten poles in length, or longer, according to the ſtrength and plenty of the water.

It is obvious from this deſcription, that as the water in this kind of meadow is not uſed again and again, in *one pitch*, as in the catch meadow, that this method is only applicable to large ſtreams, or to valleys ſubject to floods; and as theſe ridges muſt be formed by *manual labour*, the expenſe of this kind of meadow muſt neceſſarily exceed the more ſimple method firſt deſcribed: and the hatches that are neceſſary to manage and temper the water on rivers, muſt be much more expenſive than thoſe on ſmall brooks.

The expenſe, therefore, of the firſt making ſuch a meadow as this is, will be from twelve pounds to twenty pounds per acre, according to the difficulty of the ground, and the quantity of hatch-work required: but the improvement in the value of the land by this operation is aſtoniſhing. The *abſtract value* of a good meadow of this kind, may fairly be called three pounds per acre; but its value, when taken as *part of a farm*, and particularly of *a ſheep-breeding farm*, is almoſt beyond computation; and when ſuch a meadow is once made, it may be ſaid to be made for ever, the whole expenſe of keeping up the works, and watering it frequently, not exceeding five ſhillings per acre yearly, and the expenſe of the hatches, if well done at firſt, being a mere trifle for a number of years afterwards.

It has been alledged by thoſe who know very little of water meadows, that they render the country unwholeſome by making the water ſtagnant—Daily obſervation proves the fact to be otherwiſe in Wiltſhire; and

and the reaſon is obvious. It has been already ſaid, that a water meadow is a "hot-bed for graſs;" the action of the water on the land excites a *fermentation*; that fermentation would certainly in time end in a *putrefaction*: but the moment putrefaction begins, vegetation ends. Every farmer knows the commencement of this putrefaction, by the ſcum the water leaves on the land; and if the water is not then inſtantly taken off, the graſs will rot, and his meadow be ſpoiled for the ſeaſon. The very principle of water meadows will not permit water to be ſtagnant in a water-mead country; it muſt be always kept in action to be of any ſervice: beſides, many of the beſt water meadows were, in their original ſtate, a ſtagnant, unwholeſome moraſs.

The draining ſuch land, and making it ſo firm, that the water may be taken off at will, muſt contribute to the healthineſs of the country, inſtead of injuring it.

It is frequently aſked how it comes to paſs, that although water meadows are ſo uſeful as to be almoſt indiſpenſable in South Wiltſhire, yet in other counties where they are not known, the want of them is not felt; nay, that there are even in this diſtrict many pariſhes who have none, and even breed lambs without them? To this I anſwer, that the fair queſtion is not, "How do other counties do without them?" but "how could the farmers of this diſtrict, who are happy "enough to have water meadows, purſue their preſent ſyſtem of ſheep-breeding, if thoſe meadows were "taken away?" A ſyſtem which I do not heſitate to ſay, is more profitable to themſelves, their landlords, and the community at large, than any other that could be ſubſtituted in its room; and perhaps this queſtion cannot be anſwered better, than by exhibiting the contraſt between thoſe who have water meadows, and thoſe who have none, in the ſame diſtrict.

Every farmer who keeps a flock of ſheep, and particularly a breeding flock, in ſo cold and late-ſpringing a diſtrict as South Wilts, knows and feels the conſequences of the month of april. "That month *between hay and graſs*, in which he who has not water meadow for his ewes and lambs, frequently has *nothing*!" The ewes will bring a very good lamb with hay only; perhaps a few turneps are preſerved for the lambs, which, in a very favourable ſeaſon, may laſt them through march; but if they are then obliged to go to hay again, the ewes ſhrink their milk, the lambs "pitch and get ſtunted," and the beſt ſummer food will not recover them. To prevent this, recourſe is had to feeding the graſs of thoſe dry meadows that are intended for hay, the young clovers, and frequently the young wheat; in fact, every thing that is green—And who will pretend to eſtimate, what is the loſs that a farmer ſuffers by this expedient?

The ray-graſs, on the expoſed parts of this diſtrict, is ſeldom "a bite" for the ſheep, till near may-day. If the ſeaſon ſhould permit any turneps to be kept till that time (which can ſeldom be depended upon), they are not only of little nouriſhment to the ſtock, but they exhauſt the land ſo as to prejudice the ſucceeding crop. And it ought to be remarked by the way, that in many parts of this diſtrict, the ſoil is not at all favourable to the production of turneps. It therefore neceſſarily follows, that a farmer, under theſe circumſtances, has *no certain reſource* to ſupport his ſtock during this month, but hay—and even in that he is ſometimes diſappointed, by having been obliged, in the preceding ſpring, to feed all the land which he had laid up for a hay crop: he is then obliged to buy hay, and that frequently at the diſtance of many miles. And to add to his diſtreſs at this critical time, his young ewes are then brought home from wintering, to be kept nearly a month on hay alone.

In this month, which ſo often ruins the crops, and exhauſts the pockets of thoſe ſheep-breeding farmers, who have no water meadows, the water-mead farmers may be truly ſaid to be "in clover." They hain up their dry meadows early, ſo as almoſt to inſure a crop of hay; they get their turneps fed off *in time* to ſow barley, and have the vaſt advantage of a *rich fold* to manure it. They ſave a *month's hay*, and have no occaſion to touch their field graſs till there is a good bite for their ſheep; and their lambs are as forward at *may-day*, as thoſe of their leſs lucky neighbours are at *midſummer*. And after all, they are almoſt certain of a crop of hay on their water meadows, let the ſeaſon be what it will.

Management of Water Meadows.

As ſoon as the after-graſs is eaten off as bare as can be, the manager of the mead (provincially "the drowner") begins cleaning out the main drain, then the main carriage, and then proceeds to "right up the works," that is, to make good all the water carriages that the cattle have trodden down, and open all the drains they may have trodden in, ſo as to have one tier or pitch of work ready for "drowning," and which is then put under water (if water is plenty enough), during the time the drowners are righting up the next pitch. In the flowing meadows this work is, or ought to be, done early enough in the autumn, to have the whole mead ready to catch, if poſſible, "*the firſt floods after michaelmas*," the water being then "thick and good," being the *firſt* waſhing of the arable land on the ſides of the chalk hills, as well as of the dirt from the roads, &c. &c.

The length of this autumn watering cannot always be determined, as it depends on ſituations and circumſtances; but if water can be commanded in plenty, the rule is to give it a "thorough good ſoaking" at firſt, perhaps a fortnight or three weeks, with a dry interval of a day or two, and ſometimes two fortnights, with a dry interval of a week, and then the works are made as dry as poſſible, to encourage the growth of the graſs. This firſt ſoaking is to make the land ſink and pitch cloſe together; a circumſtance of great conſequence, not only to the *quantity* but to the *quality* of the graſs, and particularly to encourage the ſhooting of the new roots which the graſs is continually forming, to ſupport the forced growth above.

While the graſs grows freely, a freſh watering is not wanted, but as ſoon as it flags, the watering may be repeated for a few days at a time, whenever there is an opportunity of getting water, always keeping this fundamental rule in view, "*to make the meadows as "dry as poſſible between every watering*;" and to "*ſtop the water, the moment the appearance of any "ſcum on the land, ſhews that it has already had water "enough.*"

Some meadows that will bear the water *three weeks* in october, november, or december, will, perhaps, not bear it a *week* in february or march, and ſometimes ſcarcely *two* days in april or may.

In the catch meadows watered by ſprings, the great object is to keep "the works of them" as dry as poſſible between the intervals of watering; and as ſuch ſituations are ſeldom affected by floods, and generally have too little water, care is neceſſary to make the moſt of the water by catching and routing it as often as poſſible; and as the *top works* of every tier or pitch will be liable to get more of the water than thoſe lower down, care ſhould be taken to give to the latter a *longer time*, ſo as to make them as equal as poſſible.

It has already been ſaid, that the great object in this diſtrict of an early crop of water meadow graſs, is to enable the farmer to breed early lambs.

As ſoon as the lambs are able to travel with the ewes, (perhaps about the middle of march) they begin to feed the water meadows. Care is, or ought to be, taken, to make the meadows as dry as poſſible for ſome days before the ſheep are let in.

The graſs is hurdled out *daily* in portions, according to what the number of ſheep can eat in a day, to prevent their trampling the reſt, at the ſame time, leaving a few open ſpaces in the hurdles for the lambs to get through, and feed forward in the freſh graſs. One acre of *good graſs* will be ſufficient for five hundred couples for a day.

On account of the quickneſs of this graſs, it is not uſual to allow the ewes and lambs to go into it with empty bellies, not before the dew is off in the morning.

The hours of feeding are uſually from ten or eleven o'clock in the morning to about four or five in the evening, when the ſheep are driven to fold, the fold

being generally at that time of the year on the barley fallow. And the great object is to have water-mead grass, sufficient for the ewes and lambs, till the barley sowing is ended.

As soon as this first crop of grass is eaten off by the ewes and lambs, the water is immediately thrown over the meadows, (at this time of the year two or three days over "each pitch," is generally sufficient) and it is then made perfectly dry, and laid up for a hay crop. Six weeks are usually sufficient for the growth of the crop. It seldom requires eight; and there have been instances of great crops being produced in five.

The hay of water meadows, being frequently large and coarse in its nature, it is necessary to cut it young; and if made well, it then becomes of a peculiarly nourishing milky quality, either for ewes or dairy cows.

The water meadows are laid up for a second crop, in *some instances*; but this is only usual when hay is scarce; not that it is supposed to hurt the land, but the hay is of that herbaceous soft nature, and takes so long time in drying, that it is seldom well made. It is usually of much greater value to be fed with dairy cows. And for that purpose a flush of after-grass, so early and so rank, will be precisely of the same comparative service to the dairy, as the spring feed has been described to be for ewes and lambs.

The cows remain in the meadows till the "drowner" begins to prepare for the winter watering.

Water meadows are reckoned to be perfectly safe for sheep in the spring, even upon land that would rot sheep, if it was not watered, but in the autumn the best water meadows are supposed to be dangerous. But the circumstance is rather an advantage, than a disadvantage, to this district, as it obliges the farmers to keep a *few dairy cows*, to feed the water meadows in autumn, and to provide artificial grasses, or other green crops for their sheep, during that period.

From what has been so repeatedly urged, on the necessity of making water meadows *dry*, as well as wet, every reader must have inferred the advantage of having them, if possible, on "*a warm absorbent bottom.*"

The bottom or sub-soil of a water mead, is of much more consequence than the quality or the depth of the top soil.

Not but that land on peaty or clay bottoms, may be considerably improved by watering; and there are many good water meadows on such soils, but they are not so desirable on account of the difficulty of draining the water out of them, and making them firm enough to bear treading.

A loose gravel, or what, perhaps, is still better, a bed of broken flints, with little or no intermixture of earth, wherever it can be obtained, is the most desirable bottom.

On many of the best water meadows in this district, where the bottom is a warm, absorbent gravel, or rather a bed of broken flints; the soil is not six inches deep, and that depth is quite sufficient, in those seasons when water is plenty, as the grass will root in the warm gravel in preference to the best top-soil whatever, and such meadows always produce the earliest grass in the spring. Nor is it so very material, of what *kinds of grasses* the herbage is composed, when the meadow is made. *That kind* will always predominate, which *agrees best with the soil and the water*, provided the supply of water is regular and constant *every winter*, otherwise *that kind* will predominate which will bear *wet and dry*, and some of the worst grasses, in their native state, will become the best when made succulent by plenty *of water*.

Nature has given a striking lesson on this subject in this very district, viz. In the two small meadows at Orcheston (six miles north-west of Amesbury), usually called the "Wiltshire *Long Grass* Meads."

These meadows adjoin together, and contain, in the whole, only two acres and an half, and yet the crop they produce in a favourable year is so immense, and of so good a quality, that the tythe hay of them was once (according to the information of the tenant) sold for five guineas.

Much has been said, and little understood, about those meadows, and the grass they produce.

Many proposals and attempts have been made to propagate the grass, and many skilful botanists have returned from the spot, without finding out *which was the long grass*, its appearance being so very different in different seasons.

It has not been till lately, that it was discovered by Mr. Sole, of Bath, and communicated to the Bath Society, that the greatest part of the herbage of these meadows, was nothing more than the "black couch, or couchy bent." ("Agrostis "Stolonifera") one of the worst grasses, in its native state, the kingdom produces, and the peculiar plague of farmers in this particular district. It usually abounds in such arable land as is too poor to bear the white couch ("Triticum repens"), and is the general and almost only herbage of the old burnbeaked worn-out downs; and in that situation is of that coarse, hard, wiry nature, that no cattle will eat it. It forms a thick tough rug over the land, that preserves itself, and kills every thing else. But in these meadows, when abundantly fed with water, it is of a juicy, succulent, nourishing quality, *as grass*, and makes the most desirable *hay* in the district, particularly for sheep.

These meadows lie in the upper part of the bourn that runs from Tillhead to Stapleford, and in some winters the rivulet that passes through them is very inconsiderable. They are not laid out in regular form for watering, the supply of water being too irregular, but depends on the floods entirely; and being situated at a sharp turn of the valley, which is narrow at that spot, the water makes an eddy, and deposits its sediment upon them. The bottom is almost an entire bed of loose flints, so that the roots shoot freely in it, and produce strong succulent shoots, which fall down, and taking root at the joints, shoot out, and drop, and root again, so that the stalk is frequently eight or ten feet in length from the original root, and though the crop is exceedingly thick on the ground; it is, perhaps, not eighteen inches high.

Although this grass is most abundant in these two meadows, it is also very predominant in the greatest part of the meadows below it, on the same stream, and whenever the winters are productive of floods, the grass in all of them is abundant in quantity, succulent and juicy in quality, and the hay exceedingly nutritive. But in a scarce year of water, their produce is very small indeed, and that of a very bad quality.

On examination of other meadows, in different bourns of this district, the same grass appears uniformly to abound in those that are *situated near the spring-heads*, and which, in some years, have plenty of water, and in some none at all: the same remark is as uniformly made on its variation in quantity and quality, *according to the wetness or dryness of the winter*; and the most probable way of accounting for it, is, "*That it is almost the only grass, common to water "meads, that will stand wet and dry.*" For though it will live, and indeed flourishes most, when under water, yet no dry weather will kill it.

The Flooding of Meadow land is also of great importance in Dorsetshire, where the proportion of water meadows is very great, and no where better managed, upon the same principle as in Wiltshire. The early vegetation indeed produced by flooding is of such consequence to the Dorsetshire farmer, that without it, their system of managing sheep would be almost annihilated.

Their water-meadows are formed in wide beds, with channels for the water to run between; and the descent is so well taken care of, that the water is always in motion, and is never suffered to ferment or stagnate: at the same time great care is taken, to have a sufficient quantity of underground drains to carry off the springs, and make the boggy parts sound, by which means, no sooner has the water passed off, than the land becomes sufficiently dry to be pastured by sheep, from the middle of march to the first or second week in may; when being again watered for several weeks, it is fit to

mow about the beginning of July, and produces two tons of hay on an acre upon an average. The hay being off, it is again watered till the beginning of September, by which time it is full of grass, and supports the dairy cows till Chriſtmas. Sheep are never turned on in the autumn, rotting being conſidered as inevitable at that ſeaſon.

No manure is ever put on theſe meadows. The firſt making coſts from four to ſix pounds an acre: afterwards they are attended with ſmall expenſe and trouble, in proportion to the profit. The hay however is not much eſteemed for its quality in feeding beaſts, and is therefore generally given to cows and ſheep in the winter.

The rivers in Dorſetſhire are particularly adapted to favour the proceſs of flooding land, being frequently divided into many ſmall ſtreams, which are in general ſhallow, but quick and rapid; by which means they are eaſily diverted, and a greater proportion of land can be flooded than where a river runs through a country hurled below its banks, in one dead ſtream only. The greateſt part of the watered meadow, which is now rented near towns from 20s. to 3l. an acre, and with ſtums at 35s., without this improvement, would not be worth more than 10s. or 12s.

The proceſs of watering meadows, with drawings, has been deſcribed by Mr. George Boſwell of Piddletown, in Dorſetſhire, in a pamphlet publiſhed on this ſubject.

Even where there is no river or brook, land floods, the waſh of roads, the ſoak of the farm-yard, &c. may frequently be uſed for this important purpoſe with ſucceſs[1].

Irrigation is alſo well underſtood in Hampſhire, where the rents of watered meadows riſe from 40s. to 3l. and even 5l. an acre. Thoſe which are on gravelly and chalky ſoils being much ſuperior to thoſe on peat. They are managed and fed as above deſcribed in Wiltſhire and Dorſetſhire. Without watering they would not be worth more than 20s. an acre; and with it their produce of hay, with ſpring and autumn food, is eſtimated at 5l. Land with a peaty boggy bottom, yielding nothing but ſedge, has been advanced from 3s. or 4s. to 40s. rent an acre. Theſe ſoils however rot univerſally in ſummer and autumn, and probably would do ſo in ſpring, if any thing elſe were turned in except ewes with lambs by their ſide, for ewes that give milk never rot: but on dry ſound ſoils they affirm here that ſheep do not rot at any time[2].

The farmers in Hampſhire are ſo aware of the great advantages ariſing from water-meadows, that in many inſtances they have been at a conſiderable expenſe in purchaſing a ſupply of water, beſides the firſt expenſe of from 5l. to 6l. an acre, excluſive of the continual repair of the ſluices, &c.[3]

The benefit to be derived from the flooding of land is alſo well underſtood, and the operation judiciouſly performed, in Brecknockſhire. Where, in moſt parts, the brooks are formed by ſprings, iſſuing from the hills, at different degrees of elevation, from one to twelve hundred feet above the beds of the two main rivers: excepting therefore the detached hills, interſperſed through the middle of the county, moſt of it might be watered, if the intermixture of property did not hinder.

Sand being the prevailing ſoil here, this land is wonderfully well adapted to receive benefit from being flooded with any water that is not charged with metallic particles.

They reckon it of great importance to catch the firſt water of a flood after a long drought; more eſpecially if the water be collected from common hills or other paſture grounds that are hanging, or ſide lands where ſheep and cattle have paſtured; their dung, and the fine particles of earth being all waſhed off by the firſt autumnal floods.

This country abounding in ſwells, is in a peculiar degree adapted to derive every advantage from flooding; becauſe the water moves quickly off, as ſoon as it has done its buſineſs.

If the land be ſteep, a ſmaller quantity of water is ſuffered to go over it at a time, leſt the water ſhould carry along with it ſome particles of the looſe earth.

They prefer clear water from the ſpring for their ſandy land, but brook or river water for clay.

The farmers are very ſenſible of the benefit of having water from the farm yard turned over their meadows, and they are very careful to have the field under the houſe always a meadow. The good effects of the droppings from the farm-yard and fold upon this ſandy land are aſtoniſhing.

When water from lime-ſtone can be had, it is preferable to any other: and water from different ſprings is beneficial in very different proportions[4].

The late famous Mr. Bakewell of Diſhley ſtands foremoſt in the Midland Counties as an improver of graſs-lands by watering.

Formerly a ſuite of meadows, lying by the banks of the Soar, received conſiderable benefit from the water of the river judiciouſly ſpread over them in time of floods. But now not only theſe meadows, but near a hundred acres of higher land, lying entirely out of the way of natural floods, are watered on Mr. Boſwell's principle.

Mr. Bakewell diverted to his purpoſe a ſmall brook, the natural channel of which ſkirted the fartheſt boundary of his farm; falling with a conſiderable deſcent down a narrow valley. It is therefore turned, at the higheſt place that could be commanded, and carried round the point of a ſwell, which lies between its natural bed and the homeſtead. This not only commanding the ſkirts of the hill by watering, but ſupplying the houſe and farm offices with water; filling a drinking pool for his cattle; a waſh-pool for ſheep; floating down his turneps from the field to the cattle ſheds; &c.[5].

As to thoſe meadows which cannot be flowed, there ſhould be the ſame care taken to weed and roll them, as has been directed for the Water Meadows; as alſo never to let heavy cattle graze upon them in winter when they are wet; for the cattle will then poach them, and greatly injure the graſs; therefore theſe ſhould be fed down as cloſe as poſſible in the autumn, before the heavy rains fall to render the ground ſoft; and thoſe paſtures which are drier, may be kept to ſupply the want of theſe in winter; and where there are not cattle enough to eat down the graſs in time, it will be much better to cut off what is left, than to ſuffer it to rot upon the ground, for that will prevent the graſs from ſhooting early in the ſpring, but where people have not cattle enough of their own to eat down the graſs in time, they had much better take in ſome of their neighbours, than ſuffer their fog (as it is called) to remain all the winter. When theſe meadows are fed in the autumn, the greater variety of animals are turned in, the cloſer they will eat the graſs; and I am fully convinced, the cloſer it is eaten, the better the graſs will come up the following ſpring; and, if during the time the cattle are feeding, the meadows are well rolled, the animals will eat the graſs much cloſer than they otherwiſe would.

Thoſe perſons who are beſt ſkilled in this part of huſbandry, always dreſs their meadows every other, or at leaſt every third year, without which it is in vain to expect any good crop of hay; but the generality of the farmers are ſo much diſtreſſed for dreſſing to ſupply their corn land, as not to have any to ſpare for their meadows, they are therefore content with what the land will naturally produce, rather than take any part of their manure from their arable ground. But this is a very imprudent piece of huſbandry; for if land is to be annually mowed for hay, it cannot be ſuppoſed that it will produce a good crop long, unleſs proper dreſſings are allowed it. And when ground is once beggared for want of manure, it will be ſome years before it can be recovered again. See PASTURE.

[The ſcourings of ditches, mud of ponds, and almoſt any earth, form good dreſſings for meadow lands, if ſuffered to lie, and well turned over. Theſe, together with alternate mowing and feeding, will in general keep meadows in heart, without robbing the arable land.]

Draining.

The Draining of land is another great improvement, for though meadows which can be overflowed produce a much greater quantity of herbage, yet where the wet lies too long upon the ground the graſs will be four and coarſe, and ſo overrun with ruſhes and flags as to be of ſmall value. Cold ſtiff clays are moſt liable to this, where the water cannot penetrate, but is contained as in a diſh; ſo that the wet which it receives in winter continues till the heat of the ſun exhales it.

The method of draining ſuch lands is to cut ſeveral drains acroſs them where the water is ſubject to lodge; and from theſe croſs drains to make others, to carry off the water to ponds, brooks or rivers, in the lower parts of them. Theſe drains need not be made very large, unleſs the ground be very low, and ſo ſituated as not to be near any outlet; in which caſe large ditches ſhould be dug at proper diſtances, in the loweſt part of the ground, to contain the water; and the earth which comes out of theſe ditches ſhould be ſpread on the land, to raiſe the ſurface. But where the water can be conveniently carried off, under-ground drains ſhould be made at proper diſtances, which may empty themſelves into the large ditches.

The uſual method of making under-ground drains, is to dig trenches, and fill the bottoms with ſtones, bricks, ruſhes or buſhes; covering them over with the earth dug out of the trenches. But when there is a flood, theſe drains are often ſtopped by the ſoil which the water brings down with it.

The beſt method of making theſe drains is, to dig the principal ones three feet wide at top, ſloping them down for two feet in depth, where there ſhould be a ſmall bank left on each ſide, upon which croſs-ſtakes or bearers ſhould be laid, and below this fet-off an open drain ſhould be left, at leaſt one foot deep, and ten or eleven inches wide. Smaller drains of ſix or ſeven inches wide, and the hollow under the buſhes eight or nine inches deep, ſhould be cut acroſs the ground, to diſcharge the water into the large drains. The number and ſituation of theſe muſt be in proportion to the wetneſs of the land, and the depth of earth above the buſhes muſt be proportioned to the intended uſe of it; for if the land is to be ploughed, the drain muſt not be ſhallower than fourteen inches, but for meadow land, one foot will be enough: for when the buſhes lie too deep in ſtrong land, they will have little effect, the ground above binding ſo hard, as to detain the wet on the ſurface. The drains being dug, the larger ſticks of the bruſh-wood ſhould be cut out to pieces of ſixteen or eighteen inches in length, to lay acroſs upon the ſide banks of the drain, at about four inches diſtance; and the ſmaller bruſh-wood, furze, broom, heath, &c. ſhould be laid lengthwiſe pretty cloſe over theſe, with ruſhes, flags, &c. on the top of them, and then the earth, to cover the whole.

Such drains will continue good many years, and the water will find an eaſy paſſage through them. Where there is plenty of bruſh-wood they are made at an eaſy expenſe; but where wood is ſcarce they are very chargeable. In this caſe cuttings of willow or black poplar might be planted in moiſt places, which would furniſh bruſh-wood for this purpoſe in four or five years.

In countries where there is plenty of Stone, that is the beſt material for making under-ground Drains: for when theſe are properly made, they will never want repairing.

The beſt time for making theſe drains is about michaelmas, before the heavy rains of autumn fall, becauſe the land being then dry, the drains may be dug to a proper depth.

When the drains are finiſhed, and the water carried off the land, pare off the ruſhes, flags, &c. lay them in heaps to rot, and they will afford manure. Plough the ground to deſtroy the roots of noxious weeds; and if it be laid fallow for one ſeaſon, and ploughed two or three times, it will greatly mend the land. Spread the rotten ruſhes and flags over it, and ſow graſs ſeeds.

Some perſons burn the rubbiſh that is pared off the land, and ſpread the aſhes.

[This practice of under-draining land both for meadows and the plough, has been long practiſed in Eſſex.

Their method of opening the principal drains is to plough four furrows, throwing two each way, the two inſide furrows being ploughed deeper than the others. After the plough, the earth is ſunk a ſpit deep with a common ſpade, and afterwards another ſpit with a land-ditching ſpade, called a griping ſpade. Laſt of all, a ſcoop is made uſe of to take out the looſe earth. This drain, when completed, is about two feet deep, or from twenty to twenty-ſix inches: the breadth at top juſt wide enough to admit a man to work in, and at bottom as narrow as poſſible, not more than two inches. In the ſubordinate drains, the ſpit with the common ſpade is omitted, they are therefore not more than eighteen inches deep. The drain is filled up as high as the top of the ſpade-work, with bruſh-wood at the bottom, and a piece of wood as big as a man's leg, on the top; a little ſtraw is ſhaken over that, and the remainder of the drain is filled up with earth. The greater the proportion of wood, and the harder the earth is preſſed in, the longer will be the duration of the work. The wood muſt be ſuch as runs pretty free in its branches: Elm, Alder and Sallows are as good as any; but Black-thorn is the moſt durable. In very ſtiff land, ſtraw, ſtubble or haulm only will be ſufficient for the purpoſe.

The duration varies from twelve to twenty-five years, and ſome drains filled with ſtraw have been known to laſt much longer.

The expenſe, with buſhes, amounts, on an average, every thing included, to two guineas, or 45s. an acre; the men being paid three ſhillings a rood rods for the work. The diſtance between the drains is uſually from five and a half to eight yards.

The principles to be attended to in this mode of draining are—firſt, to get a good outfall or diſcharge; and ſecondly, to draw all the drains obliquely acroſs the deſcent of the ground, not right down, not right acroſs the fall. A great error in this mode of draining has frequently been committed in marking out and making numerous drains acroſs the ſides of ſpringy hills, which might in many caſes be drained completely by a ſingle drain, judiciouſly diſpoſed, on Mr. Elkington's principle[1].

In Devonſhire, drains are made from four to twelve feet in depth, and are never judged to be well done, unleſs they are dug to the bed of gravel. On this a gutter is built, with a wall of ſtones on each ſide the trench, leaving between the two walls an opening of three, four or ſix inches, in proportion to the ſize of the ſpring, and carefully covered on the top with flat ſtones. On theſe covers the ſmall ſtones gathered off the adjoining lands are thrown, from three to ſix inches or more in thickneſs; lining the top with fern, ſtraw, furze, &c. and filling up with the mould thrown out. Theſe ſpringy are frequently conducted to a pond, and made ſome other uſe of for watering the land, &c.[2]

In peat countries, pieces of peat of the uſual ſhape and dimenſions, are pierced with a kind of punch, when wet, by which a hole is left about three inches ſquare, a little arched at the top; they are then left to harden in the air, and when fit are placed ſide by ſide for a drain[3].

When bricks are uſed for drains, if the ground be ſoft and ſpungy, the bottom of the drain is laid with the bricks placed acroſs; tiles or ſlates will anſwer the purpoſe. Over theſe, on each ſide, two bricks are laid

[1] Kent's hints, 17. Young's agr. ſurv. of Suffolk, 22.
[2] Agric. ſurv. of Devon, by Fraſer, 44.
[3] Lancaſhire, 58.

flat,

flat, one upon the other: this is covered with bricks laid flat. The bricks ſhould be ten inches long, four broad and three thick.

This work is too expenſive, unleſs a drawback might be allowed on the heavy tax upon the material.

When the bottom of the trench is firm and ſolid, as in clay or marl, no bricks need be laid in the bottom: the ſides are then formed by placing one brick edgewiſe, inſtead of two laid flat. This is much cheaper, and in ſuch land equally durable [1].

Double bricks, with a hollow through the middle, form a good drain, which is laid very expeditiouſly.

Where ſtone is plentiful and near at hand, no material is ſuperior to it for this purpoſe. Theſe drains are in general made larger than thoſe with brick; the bottom being at leaſt eight inches wide.

In Wiltſhire their ſtone-drains are in general ten or twelve inches in width, with perpendicular ſides. Sometimes the ſtones are ſo placed as to leave a watercourſe at bottom, by ſetting two flat ſtones triangularly, to meet at the points: but it is a better way to cover the bottom with a flat ſtone, and then to put three other flat ſtones upright, leaving the water to find its way between them; in both caſes filling up the reſidue of the drain to the top, or near it, with looſe ſtones.

Where only ſmall round ſtones can be got, the drain may be made taper, from nine inches at top to nothing at bottom, and about three feet deep; filling it up with the ſmall ſtones firſt, and finiſhing with a thin turf at top. Where gravel is more plentiful, it is found to anſwer the purpoſe very well, if ſcreened or waſhed.

In all caſes, the general opinion is, that thoſe drains laſt longeſt, which have the leaſt or narroweſt waterway left at bottom; the force of the water being then ſufficient to clear away any little obſtacles [2].

Where none of the above materials are to be had, there is ſtill another ſort of covered drain which may be adopted in a ſtiff tenacious ſoil. This is made with turfs or ſods, and beſides being the cheapeſt, is as laſting as any, where the land is ſufficiently cohæſive. The inverted turf is either put upon a ſhoulder, leaving a hollow part under it, and the remainder of the drain is filled up with the earth that came out of it: or the drain is cut out in a wedge, or the form of the letter V, and when the earth is taken out, ſix or eight inches of the bottom part of the wedge are cut off, and the remainder is filled up. If a few ruſhes were put round the bottom of this wedge, ſo as to keep the lower part from dropping, and the ends of the ruſhes were drawn upwards, between the ſides of the drain and the wedge, it would be an improvement. Care muſt be taken, to keep off all cattle till theſe drains have had time to ſettle [3]. The entrances ſhould have a fence of brick or ſtone to ſecure them. Their aperture at top ſhould be eighteen inches, their depth thirty inches. The ſtrength with which the ſods are ſupported, and their depth in the ground, being at leaſt twelve inches, will effectually prevent their removal by any weight on the ſurface; and ſecure them from all effects of the weather.

In looſe crumbly ſoils, where the wetneſs does not ariſe from the retention of water by an underſtratum of clay, but from ſprings, theſe drains are improper: but when the wet is prevented from paſſing off by clay or marl, theſe ſod drains are excellent [4].

Thus clay ſoils, through which water can neither paſs from the ſurface to the bottom, nor from the bottom to the ſurface, muſt be relieved from too much wet by ſurface drains: and where the ſurface is porous above, but tenacious below, ſome of the modes of hollow-draining deſcribed above may be ſucceſsfully practiſed. But theſe will not effectually cure lands rendered wet by waters confined beneath the ſurface, and attempting to riſe in the manner of ſprings, which is the great object of Mr. Elkington's ſyſtem of draining; and this he obtains not by uſing palliatives, but by getting the command of the ſubterraneous waters themſelves, and thus completely and radically cutting off the cauſe of the miſchief.

The principal uſe of Mr. Elkington's ſyſtem is that of draining bogs, and though it may be applied to any ſpringy lands, yet it is in this point of view the moſt important; both becauſe immenſe tracts of valuable land, which are of a moraſſy nature are loſt to the community, from an idea that it is impoſſible to drain them; and land of that nature and value, in proportion to its extent, may be drained at the ſmalleſt expenſe, and when drained becomes perhaps the moſt valuable of any.

When a bog or moraſs is to be drained, the direction in which the trench is to be dug is firſt to be aſcertained. This is the moſt difficult part of the whole buſineſs, and cannot be fully underſtood but from much practice. The following rules however may be of ſervice.

1. The whole depending upon the nature of the bog to be drained, and the ſtate of the adjacent country, the neighbouring ſtrata muſt be aſcertained as far as poſſible, whether they be of ſtone, gravel, ſand or marl; for the water muſt be lodged in one of theſe, and it is neceſſary to aſcertain in which.

2. The trench muſt be directed ſo as to fall in with the bottom of the bed which occaſions the miſchief, and the particular ſpot where the main ſpring lies. One ſpring may probably occaſion the whole bog, which having no proper vent, forces the water through many ſmall veins, even to a great diſtance, making the whole a ſwamp. By draining the main ſpring, the others follow of courſe.

3. If there are various beds through which water iſſues, ſtone is to be preferred for draining the whole; the water being much more eaſily drawn through that, than through gravel, ſand or marl; conſequently by draining the ſpring there, the whole water which communicates therewith flows to it; water always preferring a ſtraight or clear to a crooked channel. But in ſtone beds the trench ought to be made from ſix to eight yards from the tail of the bed, or the place where the rock ends, becauſe in limeſtone and other rocks, the tail is harder than any other part of the rock, and there are few if any fiſſures in it; but by going a few yards above, you get into a ſofter part of the bed, and the water is more acceſſible. The tail of theſe beds may often be found at a point or promontory jutting out from the adjacent heights.

4. The trench in general ſhould be directed in a line with the bottom of the hill, becauſe it makes the beſt ſeparation between the upland and the meadow incloſures, and the ſpring can beſt be intercepted. The trench however muſt be carried in the line of the ſpring, or near it; for if it diverges from it any diſtance, all proſpect of reaching the ſpring, by tapping or otherwiſe is loſt.

5. It is better to make a new trench, than to tap the ſpring in any old brook or run of water, where that may be practicable; for though the ſpring, when once it burſts out, has force enough to throw up any ſtones, ſand, &c. that may accidentally fall into it, yet brooks in a flood may bring down ſuch immenſe quantities as completely to choak up the ſpring; and ſo much caution is neceſſary to prevent any riſk of ſuch a circumſtance, that when the trench croſſes any runlet of water proceeding from a ſmall brook, or from a collection of ſurface water, the trench is puddled ſo as to receive it, leſt it ſhould blow up and deſtroy the works.

Laſtly, the general line of direction being fixed on, and the trench marked out, begin at the bottom or loweſt level, carrying the trench gradually up under guidance of the ſpirit level: a few inches fall in a hundred yards will be ſufficient.

In digging the trench, no tools but thoſe of the common ſort are made uſe of, and common labourers can carry it on under an experienced foreman or overſeer. The auger, which muſt often be uſed for tapping the ſpring, may be from an inch and half to two inches diameter, and is applied in the ordinary manner; if in boring, a ſtone be met with, the auger

[1] Hunter's Eſſays, 6. 437.
[2] Agric. ſurv. of Wilts, 142.
[3] Hunter's Eſſays, 6. 445. Kent's Hints, 26.
[4] Hunter, 443.

must be taken off, and a chiſſel or punch ſcrewed on, to penetrate ſo hard a ſubſtance.

Sometimes the ſpring is cut off by the trench alone; but in many caſes it lies greatly below the level of the trench, and then it is neceſſary to uſe the auger for tapping the ſpring. Mr. Elkington bored an auger hole near Tamworth, thirty feet in depth, which threw up three hogſheads of water in a minute, and completely drained all the neighbourhood. If it be certain that all the water in the ſpring flows through the hole made by the auger, the trench may be ſtopped; but if not, it muſt be carried farther, and the auger again made uſe of.

The trench being made, and the ſpring cut off, either by tapping or otherwiſe, it is then neceſſary to determine whether the drain ſhould be open or covered. If it can at the ſame time be made a fence, it had better be open; if not, it ſhould be covered. No apprehenſion need be entertained of the holes made by the auger being filled up, in either caſe, unleſs other waters be admitted; becauſe ſuch is the force of the ſpring, that it will throw up any ſtones, earth or other ſubſtances that might accidentally get into it, and can be injured by nothing but great quantities coming upon it at once.

This ſyſtem of draining is ſometimes attended with extraordinary conſequences. By it, not only the land below the natural ſpring, or even above the artificial ſpring, is drained, but the waters from the neighbouring heights, finding a new and eaſier channel, abandon the places to which they formerly went, and thus a tract of country may be drained, without any apparent communication with the ſpring intended to be drained, or the trench made to it. Nay a drain made on one ſide of a hill has been known to make ſprings and wells on the other ſide quite dry, by opening an eaſier channel, to which the water naturally draws.

This practice may not only ſerve the purpoſe of draining land, but the complete command of a treaſure of water being thus obtained, it is probable that it may in many caſes be uſed for flooding land, for mills and navigations, for ſupplying private houſes, and even villages and towns with wholeſome water. A country loſes that dampneſs which is ſo pernicious to the health of the inhabitants, and its attendant, a foggy atmoſphere. The produce of the ſoil is conſiderably increaſed in quantity, and improved in quality. The rot, that deſtructive malady, to which ſo many millions of ſheep fall a ſacrifice, is prevented. In ſhort, the advantages of draining are ſo many, that it is aſtoniſhing that the principles of the art have not been better underſtood, and that greater and more extenſive exertions have not been made in ſo ſalutary and beneficial a practice [a].

The method of draining ſpringy and boggy lands by tapping, ſeems to have been hit upon about the ſame time by Dr. Anderſon and Mr. Elkington, independent of each other; the former being led to it by reaſoning, the latter by accident. It appears to have been imperfectly practiſed, antecedent to either; but Mr. Elkington has the merit of having firſt applied the auger to this buſineſs, and of having rendered this important practice ſo general as it is now become.

Leaves alternate ovate-lanceolate.

DESCRIPTIONS, *&c.*

[Stem herbaceous, erect or ſcandent, ſimple or branched; branchlets and leaves ſpathed at the baſe; flowers ſolitary, axillary. M. virginiana has whorled leaves, and the habit of Trillium or Paris. Juſſieu doubts whether it appertains to this genus [c].]

1. This has a ſmall ſcaly root, from which ariſes a ſingle ſtalk about eight inches high. There is one whorl of leaves at a ſmall diſtance from the ground, and at the top are two leaves ſtanding oppoſite: between theſe come out three ſlender peduncles which turn downwards, each ſuſtaining one pale herbaceous flower with a purple pointal. Miller follows Linnæus in placing it in this genus, though the characters do not exactly agree, the corolla being either polypetalous or cut into many ſegments, and having but five ſtamens. He ſpeaks however with diffidence, it being ſome years ſince he ſaw the flowers.

[He probably therefore cultivated it ſeveral years before 1759; though the era of its cultivation is ſet down for 1768 in the Kew catalogue.—It is a native of Virginia, and flowers in june.]

2. This has a root compoſed of ſeveral oblong knobs, which unite at the top, like that of Ranunculus; from which ariſe two or three ſtiff winding ſtalks, dividing into branches, and riſing four or five feet high, if they meet with ſupport. Leaves ſeſſile, ending in acute points, of a light green beneath, but dark above. The flowers come out from the ſide of the ſtalks, ſingly or two on a ſlender ſhort peduncle. Petals dull white. It flowers at the beginning of winter, and the ſeeds are ripe in the ſpring.

Native of the Cape of Good Hope. [Cultivated in 1702, by the Dutcheſs of Beaufort [d]. See Dracæna, and Retz. obſ. 5. p. 3. n. 49.]

3. This has a root like the preceding, but the ſtalks are not ſo ſtrong; they climb higher, but do not branch ſo much; the leaves are much longer and narrower, and are of a grayiſh colour. The flowers come out from the ſide of the branches, two or three upon each peduncle; they are of an herbaceous white colour, ſhaped like thoſe of the preceding, and appear about the ſame time, but have not produced fruit here.

Native alſo of the Cape. [Cultivated by Mr. Miller in 1752. It flowers from december to march [e].]

PROPAGATION AND CULTURE.

1. This is hardy enough to live in the open air; but producing no ſeeds here, can be increaſed only by offſets.

2. 3. Both theſe ſorts propagate freely by offſets from the roots, ſo that when they are once obtained, there will be no neceſſity of ſowing their ſeeds, which commonly lie a year in the ground, and the plants will not be ſtrong enough to flower in leſs than two years more, whereas the offſets will flower the following ſeaſon. The time for tranſplanting and parting the

[a] Young's Ann. 28. 77.

[b] Juſſieu, gen. [c] Hort. kew. [d] Ibid. [e]

roots is in july, when their ſtalks are entirely decayed, for they begin to ſhoot towards the end of auguſt, and keep growing all the winter, and decay in the ſpring. Theſe roots ſhould be planted in pots filled with good kitchen-garden earth, and may remain in the open air till there is danger of froſt, when they muſt be removed into ſhelter, for they are too tender to live through the winter in the open air; but if they are placed in a warm green-houſe, they will thrive and flower very well, but they do not produce fruit unleſs they have ſome heat in winter, therefore where that is deſired, the plants ſhould be placed in a ſtove kept to a moderate degree of warmth. During the winter, when the plants are in vigour, they ſhould be frequently but gently watered; but when the ſtalks begin to decay, they muſt have very little wet, for much moiſture will rot them while they are in an inactive ſtate; during which time, if the pots are placed where they have only the morning ſun, they will require little or no water: but when they begin to ſhoot out their ſtalks, they ſhould be removed to a warmer ſituation, and ſhould then be frequently but gently watered.

The flowers of theſe plants making no great appearance, the plants are not preſerved for their beauty, but as their ſtalks are climbing, and their leaves are in full vigour in winter, during that ſeaſon they add to the the variety in the green-houſe.

Lin. ſyſt. 694. *ſuppl.* 340. *Jacq. hort.* 1. 39. *t.* 89. *Til. piſ.* 110. (Medica.)

Legumes ſpiral unarmed, leaves ternate wedge-ſhaped toothed at the top, ſtipules briſtle-ſhaped quite entire, ſtem diffuſed.

DESCRIPTIONS, *&c.*

Theſe are herbs, except the firſt and ſecond, which are ſhrubby or fruteſcent. Leaves commonly ternate. Stipules ſmall, faſtened to the bottom of the petiole. Peduncles axillary and terminating, one-flowered, or many-flowered in ſpikes or glomerate *.

Miller has followed Tournefort in dividing this natural genus into two, from the fruit, which in his *Medica* is ſickle-ſhaped; in his *Medicago* ſpiral, ſcrew-ſhaped, or like the ſhell of a ſnail. The ſhape of the fruit being ſo variable in this genus, it is an improper baſis of a generic diſtinction.]

1. Tree Medick, named Moon Trefoil from the ſhape of the pods, and its trifoliate leaves, or Horned Tree Trefoil, as it is called by Parkinſon, is a ſhrub growing to the height of four or five to eight or ten feet, and being covered with a gray bark, the whole has a hoary appearance. The ſtem divides into many branches, with ternate leaves at each joint, on foot-ſtalks about an inch in length; there being ſeveral of theſe leaves together, the whole ſhrub is cloſely covered with them; and it is never deſtitute of leaves: the component leaflets are ſmall, lanceolate (or wedge-ſhaped, emarginate,) and hoary on their under ſide. The flowers are produced on peduncles from the ſide of the branches, four or five together, and are of a bright yellow. The pods contain three or four ſmall ſeeds.

It flowers great part of the year, and when ſheltered is ſeldom deſtitute of flowers. In the open air it begins to flower in april, and continues till december. Thoſe flowers which appear early in ſummer will have the ſeeds ripe in auguſt, or the beginning of ſeptember, and the others will ripen in ſucceſſion.

It grows in great plenty in Abruzzo, and many parts of the kingdom of Naples, where the goats feed upon it; and with their milk abundance of cheeſe is made there. It alſo abounds in ſeveral of the iſlands in the Archipelago, where the Turks uſe the wood to make handles for their ſabres; and the Caloyers or Greek monks form their beads of it. In old ſhrubs the heart is of a dark colour, and hard like ebony.

This ſhrub bids the faireſt of any to be the *Cytiſus* of Virgil, Columella and the other ancient writers on huſbandry; and being celebrated by them as an excellent fodder, has been recommended for cultivation here. But however uſeful it may be in Candia, Rhodes, Sicily, Abruzzo, and other dry warm countries, yet it will never thrive in England, (where we have alſo many plants of this leguminous tribe far more ſucculent than this) ſo as to be of any real advantage; for in ſevere froſt it is very ſubject to be deſtroyed, or at leaſt ſo much damaged, as not to recover its former verdure before the middle or end of may: (and even after a mild winter it will generally appear injured by our cold ſpring winds even at that ſeaſon; ſo that it cannot be of any uſe here for early ſpring fodder.) Beſides, the ſhoots will not bear cutting above once in a ſummer, and then will not be of any conſiderable length: and the ſtems growing very woody, the cutting of it will be very troubleſome. Upon the whole therefore it is not worth the trial, eſpecially as we have ſo many plants preferable to it: though in hot, dry, rocky countries, where few other plants will thrive, it may be cultivated to great advantage. But however unfit Tree Medick may be for uſe as fodder in England, yet for the beauty of its hoary leaves, abiding all the year, together with its long continuance in flower, it deſerves a place in every good garden and plantation, with ſhrubs of the ſame growth.

[Maranta, who has deſcribed this ſhrub, found it near Naples; Honorius Bellus, in Rhodes and the iſlands adjacent; Ray about Baie abundantly.—Gerarde, who calls it Horned Cytiſus, or Horned Shrub Trefoil, cultivated it in 1596.

2. The corolla of this is red and white variegated; the legumes have only one ſeed.

Native of Virginia *.]

3. This is an annual plant, having ſeveral ſlender branching ſtalks a foot and half long, and ſpreading on the ground. Leaflets ovate-lanceolate, entire. The flowers are produced ſingly upon ſlender peduncles from the ſide of the branches; they are ſmall and yellow. [Legumes membranaceous, ſubdiaphanous, pale, nerved with capillary radiant veſſels, ſtarted and of a leafy ſubſtance, obſcurely ſwelling at the ſeeds, ſetaceous-toothletted at each future, many-celled, not opening. Seeds four to ſix, ovate, ſtarted a little, tuberculate-wrinkled, ruſeſcent *.]

It grows naturally in Italy, (and the Levant. Ray found it about Meſſina in Sicily.) It flowers in june and july, and the ſeeds ripen in autumn.

[Cultivated by Miller in 1759.

4. This whole plant is pubeſcent. Leaves wedge-form, entire, below ſimple, above pinnate; leaflets inconſtant in number, often deficient on one of the ſides, and on the other ſmaller, and they alternate with an odd leaflet, ſometimes ſeſſile, ſometimes petioled: the ſurface of the leaves projects at the baſe of the hairs, ſo as to appear tubercled. Stipules none. Flowers at the ends of the branches, commonly by threes, very ſeldom only two together. Legume thicker, more round than in the preceding, and ſcarcely toothed at the edge *: in the middle ſlightly convex, but towards the circumference attenuated and membranaceous, ſmooth, not netted, two-celled, valveleſs. Seeds two, kidney-form, ruſeſcent *. Both Gærtner and Retzius remark, that the legumes are ſometimes not at all toothed at the edge.

Native of Spain and Italy. (Ray found it in Sicily.) Introduced in 1777, by Abbé Nolin *.

If this be Medica hiſpanica of Miller, as it probably is, then he cultivated it many years earlier. He thus deſcribes it.]

Root annual. Stalks a foot and half long, trailing. Leave pinnate, compoſed of two pairs of ſmall leaflets, terminated by one large ovate-lanceolate leaflet; they are a little hoary, and placed alternately at the joints. Flowers on long ſlender peduncles, each ſuſtaining four or five gold-coloured flowers at the top; ſucceeded by compreſſed pods, not half ſo large as thoſe of the preceding, but having hairy indentures like them.

β. Medica Cretica grows naturally in the Archipelago. This is an annual plant, from the roots of which come out ſeveral oblong leaves about two inches and a half long, narrow at their baſe, but broad towards the top, where they are rounded; theſe ſpread on the ground, and from among them come out the ſtalks, which are ſlender, about a foot long, branching out into ſmaller, having pinnate hoary leaves: thoſe on the lower part of the ſtalk have two pairs of oval leaflets, terminated by an odd one: the upper leaves

* Linn. * Gærtner. * Murray.
* Gærtner. * Hort. kew.

* Juſſieu.

are ternate. Flowers terminating, ſmall, yellow; ſucceeded by compreſſed pods, acutely toothed on the edge, and containing three or four ſeeds.

[Retzius is of opinion that this alſo is of the ſame ſpecies with the hiſpanica of Miller and circinata of Linnæus, or a variety of it.

5. Root annual. Stems decumbent, long, four-cornered. Leaves ternate: leaflets obovate, finely ſerrate, ſeldom hairy: petioles long, channelled above. Stipules ciliate-toothed. Peduncles axillary, the length of the leaf, many-flowered, elongated after flowering. Flowers like thoſe of M. polymorpha, yellow with the banner paler. Legumes in a ſhort raceme, compreſſed, keeled, veined, two-ſeeded. Seeds oblong-kidney-form, ſmooth. The plant in flower reſembles M. polymorpha, but the legumes are very different. Theſe agree very nearly in form with thoſe of M. circinata, but are only half the ſize, ſtiffer, more bent in, ſo that the end meets the pod again, which is therefore in a manner orbicular. The legume not being ſpiral, this is not a variety of M. polymorpha. It is probably a native of Germany[a].

Retzius ſuſpects that this may be the Medica italica of Miller, which he ſays] grows naturally on the ſea coaſt in ſeveral parts of Italy. It is an annual plant, with proſtrate herbaceous ſtalks about a foot long. Leaves ternate: leaflets wedge-ſhaped, towards the top ſerrate. The flowers are produced on ſlender peduncles ariſing from the joints of the ſtalk; they are about an inch long, and ſuſtain five or ſix pale yellow flowers; which are ſucceeded by ſmall thick pods, with entire borders, containing three or four ſmall ſeeds.

6. [Cultivated Medick, or Lucern has a perennial root, with annual ſtalks, ſmooth and ſtriated, from a foot and half to two feet, and even almoſt three feet in height, in good ground: branched alternately. Stipules lanceolate, awned. Leaves ternate: leaflets elliptic, entire at the baſe, but finely ſerrate towards the end; the midrib is lengthened into a point; they are ſlightly downy on their upper ſurface, ſmooth and ſtreaked with veins on the under; all on pedicels, the middle one longeſt.] The leaves are placed alternately: the leaflets are deep green, an inch and half long, and half an inch broad. [Peduncles axillary, longer than the leaves. Flowers in thick ſpikes,] from two to three inches in length, on naked peduncles, two inches long. [Each flower is on a ſhort pedicel, with an awl-ſhaped bracte at the baſe. Calyx nearly ſmooth, with five awl-ſhaped teeth, almoſt equal. Corolla purple. Legumes with two or three diſtant turns[b].]

The common colour of the flower is a fine violet purple, but Mr. Miller mentions the following varieties to have accidentally ariſen from ſeeds; viz. with pale blue, and with variegated flowers. Theſe, however, he ſays, are never ſo ſtrong as thoſe with purple flowers, and therefore are to be avoided by cultivators. [In the Flora Ruſtica the corolla, by ſome miſtake, was coloured of a red purple. Villars affirms, that the flowers are white, ſeldom greeniſh: and Krocker, that the keel is ſometimes yellow.]

It flowers in june, and the ſeeds ripen in ſeptember.

[It is ſet down as a native of many parts of Europe, even of England, where it is probably not indigenous. Linnæus aſſigns it to Spain and France. Haller does not regard it as a native of Switzerland. Pollich thinks it is indigenous of the Palatinate, becauſe it is found there, in places where it is never cultivated. Krocker ſuppoſes it to have become a denizon of Sileſia, where it is now undoubtedly found in places that have not been ſown with it. Villars ſpeaks of it as certainly wild in Dauphiné. Ray obſerved it growing ſpontaneouſly about Montpellier, and cultivated about Avignon and Geneva.

It may poſſibly have been originally a native of Europe, continuing to be diſregarded, till it was imported into Greece from the Eaſt, after Darius had diſcovered it in Media, whence its name. It is ſaid to be the principal green fodder for horſes in Perſia to this day. It has been cultivated time immemorial in the ſouthern countries of Europe; but it has not even yet gained a firm eſtabliſhment in Great Britain;] ſo as to be cultivated in conſiderable quantities, though it is evident that it will ſucceed here as well as in France or Switzerland, and that it reſiſts the ſevereſt cold of our climate. As a proof of this, Miller mentions, that ſeeds ſcattered accidentally in autumn have come up, and the plants having endured the cold of a ſevere winter, have been very ſtrong the following ſeaſon. This however does not now want proof.

About the year 1650, continues Mr. Miller, (alluding I ſuppoſe to Hartlib's queries) the ſeeds of Lucern were brought over from France, and ſown here; but whether for want of ſkill in the culture, or from reluctance to depart from the old beaten track, it was entirely neglected for many years, ſo as to be almoſt forgotten.

[In Gerarde's time, we had it only in our gardens, where it laſteth long, as he ſays, with great increaſe. Parkinſon, in 1640, informs us, that it was ſown in Spain, France, and the Low Countries, but does not hint at our having it then in England. Hartlib, in 1649 to 1651, took ſome pains to make enquiries about it in France. It is barely mentioned by Blith, in 1653, as being in great credit among the French. Woolridge, in 1668, ſays that it is commended for an excellent fodder, but does not pretend that it was then cultivated here. It ſeems to have been very little known in the time of Mr. Liſle, who is ſaid to have continued his enquiries and experiments to the time of his death in 1722. Mortimer ſpeaks of it rather by hearſay, than from any actual knowledge of it. Tull recommends its culture in his horſe-hoeing huſbandry. But Mr. Miller appears to have been the firſt who brought it into that degree of cultivation in which we find it at preſent. The attention of the public was called to it by the Rev. Walter Harte, about 1757; and by Mr. Rocque about the year 1765. The latter ſays, that a farmer in Kent had then fourteen acres of it; but that one and twenty years before there were not two hundred pounds weight of the ſeed in London. It was alſo about that time encouraged by premiums from the Society of Arts, Manufactures and Commerce[c]. My father cultivated it with ſucceſs at Streatham in Surry, during many years from 1752. It has never been my fortune to be ſituated in a ſoil congenial to it, but I have conſtantly kept it in my eye, and am firmly convinced that it is a moſt valuable green fodder, particularly for horſes, on account of its quality, quantity and earlineſs. I have ſeen it cut ſeventeen inches high on the *ninth of april*.

Lucern has been greatly celebrated for increaſing the milk of kine: but Haller, who certainly knew it well, aſſerts that cattle are apt to grow tired of it, and that they are ſubject to be blown by it. I have never heard that we have found either of theſe inconveniences in England.

With reſpect to the culture of Medica or Lucern in the ſouthern parts of Europe, the Greeks ſpeak of it from Theophraſtus to Dioſcorides, the Latins from Virgil to Palladius. Even in Italy however it ſeems to have been loſt from the time of the irruption of the barbarians, and to the moderns for ſome time, ſince Matthioli owns, in the year 1558, that he had never ſeen it growing. At the ſame time he ſays it is related, that it is abundantly cultivated in Spain, for kine and ſheep, and that it is known there by the Arabic name *Alfalfa*. In that country it is probable that it was never quite loſt. Caſtore Durante, in 1585, informs us, that it then began to be recovered to Italy, and to be ſown for the food both of horſes and cattle. In Henry the Fourth's time it was common in the South of France. Our Barnaby Googe alſo, in 1578, ſays, (from Hereſbach) that no better food can be deviſed for cattle; and that among all ſorts of fodder, that is accounted for the chiefeſt and beſt, which the people of old time, and the Italians at preſent, call *Medica*.

Mr. Harte however informs us that the Medica at firſt introduced about Rome, was not the true Lucern.

[a] Retzius. [b] Woodward, Mſ. Fl. ruſſ. [c] Fl. ruſſ. & Harte, Eſſay 2.

but the *Medicago* polymorpha, or Small-Medick; as he was affured by curious botanifts well fkilled in agriculture; and farther fays he doubts not but that this fpecies alfo affords very agreeable food; for a horfe of his breaking into his garden, devoured twenty plants of it that ftood in different beds, in a few minutes*. That however is an annual plant.

The name Lucern, Lucerne or Luzerne, by which this Medick is now generally known among us, is modern. Old Engliſh writers call it *Medick-fodder*, *Burgundy Trefoil*, *Snail Trefoil of Burgundy*, or *Snail Clover*. Hartlib and Blith firſt adopted the French name *La Lucerne*. The Germans and the other northern nations have alſo adopted the name from the French, who alſo call it *Treffe or foin de Bourgogne*, and *Grand Trefle*. The Italians name it *Medica*, *Lucerna*, and *Erba Spagna*. The Spaniards *Alfalfa*, *Mielga*, *Medica*. The Portugueze, *Lucerna and Medicagem dos paſſos*. In Perſian it is *Gaulcha*.

7. Root perennial. Stems round, ſmooth, ſlightly ſtriated, procumbent but aſcending or bending upwards towards the end, branching, two, three and ſometimes four feet in length. Leaves alternate, on ſhort petioles: leaflets lanceolate, oblong-ovate, or wedge-ſhaped, ſmooth, truncate or retuſe, toothed towards the top, entire at the baſe, the midrib lengthened into a projecting point; the two lateral ones almoſt ſeſſile, the middle one on a longer petiolet. Stipules lanceolate, acuminate, entire, or ſometimes with one or two teeth on the outer edge. Peduncles axillary, ſomewhat angular, ſtanding much above the leaf. Flowers in ſhort looſiſh racemes, each on a pedicel, with an awl-ſhaped bractæ. Calyx ſlightly pubeſcent, with equal awl-ſhaped teeth. Corolla commonly yellow. Legumes ſickle-ſhaped, not making ſeveral turns, as in cultivated Lucern, linear, ſix or ſeven lines long, and ſcarcely two broad, ſmooth or ſlightly pubeſcent, one-celled, two-valved, black when ripe. Seeds five or ſix, compreſſed, ſmooth, yellow, fixed to the interior future†. According to Gærtner there are only two or three, of an oblong kidney ſhape; and the pod itſelf is creſcent-ſickle-ſhaped or ſubſpiral.]

Miller remarks, that the ſtalks of this are ſmaller, and never riſe ſo high, as thoſe of the true Lucern, and that they are generally proſtrate; that the leaves are not half ſo broad; that the flowers are produced in ſhort roundiſh ſpikes, and are of a ſaffron colour.

Yellow Medick is common in the South of Europe, by way ſides and in dry paſtures. With us it is alſo common, in the ſandy grounds near Bury in Suffolk. Mr. Doody remarked it between Watford and Bushy. Mr. Roſe and Mr. Woodward about Norwich plentifully; Quey, Bourn-bridge, Wilbraham and Linton in Cambridgeſhire.

Linnæus has recommended it for cultivation; but Haller objected to the hardneſs of the ſtalks, and its proſtrate manner of growth. In cultivation however the ſtalks may prove more ſucculent, and in this ſtate they will ſupport each other. A ſingle plant of purple Lucern will hardly ſupport itſelf, and the ſtalks become very ſticky at bottom when it is far advanced. Upon the whole, this is probably not ſuperior to the purple Medick or Lucern. The roots ſtrike very deep, and are with difficulty eradicated.

β. Yellow Medick varies much in the colour of its flowers, which are ſometimes whitiſh, quite white, or greeniſh, as well as of different ſhades of yellow. But it is remarkable for a variety, or perhaps mule, with flowers of colours ſo different as blue and yellow on the ſame ſtalk. Caſpar Bauhin ſays, that it is found in the South of France with whitiſh yellow, green, blue, purple, black, and variegated flowers, but he does not affirm that theſe different colours occur on the ſame individual. Mr. Ray obſerved it between Norwich and Lynn, it has alſo been found about Bury, and is ſaid to be common near Norwich and Yarmouth. Ray doubted whether it might not be the true Lucern in a wild ſtate. The ſtipules in plants of the variegated variety which have come under my obſervation were much narrower than in the Yellow Medick.

If this difference ſhould prove to be permanent, it might induce us to ſuſpect that they are diſtinct ſpecies*.

8. Root annual or biennial, with few fibres, and penetrating deep into the earth. Stems trailing unleſs ſupported, numerous, about a foot long, ſomewhat angular, ſlightly hairy, branched. Leaves on very ſhort petioles: leaflets obcordate, obovate, or wedge-ſhaped, bluntiſhly toothed towards the top, the midrib lengthened out into a ſhort broad point, ſoft, pubeſcent particularly on the under ſide. Stipules ovate-lanceolate, acuminate, notched with little teeth. Flowers ſmall, yellow, from thirty to forty and upwards in a head, which is firſt roundiſh, afterwards oval. Calyx ſlightly downy, nearly as long as the corolla, with five awl-ſhaped teeth, nearly equal, but the two upper ones rather ſhorter, and more remote. Legume ſtriated and wrinkled, ſomewhat liſpid with rigid hairs, turning black when ripe. Seed ovate, ſmooth, yellowiſh†.

This plant is often confounded with ſome of the Trefoils, from which however it is ſo diſtinct in the fruit, as to be rightly placed in a different genus. The leaves and ſtalks alſo of this are frequently more hairy than thoſe Trefoils for which it may be miſtaken, except *ſubterraneum*, which is uſually ſmaller: in general, the more barren the ſoil, the more downy this plant appears; by culture it becomes much larger and ſmoother.

The flowers of M. lupulina are ſmaller and more cloſely compacted than thoſe of *Trifolium agrarium* and *procumbens*, both of which it much reſembles; nor are the ſpikes ſo exactly round as in them, but of an oval or oblong ſhape, eſpecially when ſomewhat advanced: when the ſeeds are ripe, this is diſtinguiſhed at firſt ſight by its black ſeed-veſſels*. From this circumſtance it has obtained the names of *Black-ſeed* and *Black Nonneſuch* among ſome cultivators: but it has commonly the name of *Trefoil*, when cultivated either alone or with Ray-graſs for ſheep. The old writers call it *Melilot Trefoil*. Mr. Huſſon names it *Black Medick*, and Mr. Curtis, *Hop Medick*.

It grows naturally on dry banks and hilly paſtures, chiefly in a ſandy or dry ſoil, is common in New England, and flowers in june and july.

9. The legume of this is cylindric-globular and ſpiral or like a ſnail's ſhell, with about four turns of the ſcrew, which are contiguous, and cinereous tomentoſe; the outer future is convex, defended on each ſide by very ſhort pungent diſtant ſpinules. Seeds four or five, kidney-form, yellow*.

Native of the ſhores of the Mediterranean ſea, as about Marſeilles and Tripoli. Ray obſerved it abundantly on the ſandy coaſts.]

According to Miller, it is a perennial plant, with trailing woolly branches about a foot long, divided into many ſmall branches. Leaves ſmall, downy, on ſhort footſtalks, at each joint. Flowers from the ſide and at the ends of the branches, in ſmall cluſters, of a bright yellow colour. They appear in june and july, and the ſeeds ripen in ſeptember.

10. [Root annual, oblong, branched. Stems more or leſs procumbent, ſomewhat angular, hoary, from a hand to a foot in length, ternate: leaflets roundiſh, retuſe, ſubterrate, glaucous-green, petioled; the upper ones ſmaller, ſoft, tomentoſe. Stipules entire or toothed, ſeſſile, in pairs at the baſe of the petioles. Peduncles axillary, much longer than the leaves, round, pubeſcent, forming a ſpike: flowers very ſmall, commonly yellow. Calyx ſmaller than the corolla, hirſute, green-hoary. Legumes ſhell-ſnailed, ſmall, one-celled, of different ſhades of brown or blackiſh when ripe, ciliate, aculeate or naked. Seeds ovate, ſmooth, convex on one ſide, flat on the other, lemon-coloured*.

Linnæus juſtly names this ſpecies *polymorpha*; and remarks, that like the Dog among the animals, this

* Hartz. 2. p. 8. † Woodw. Mſ. Fl. raſſ. Gærtn.

* Fl. raſſ. * Curtis, Woodw. Mſ. Linn. With.
* Curtis. * Gærtner. * Krocker.

plant

55287

plant produces numerous varieties, though not in the ſame country. Some of theſe varieties are erected into ſpecies by Miller, Gerard, Gærtner and others.

α. Stems diffuſed, ſmooth. Leaflets ſmall, triangular or wedge-ſhaped, very blunt, ſomewhat villoſe, the upper ones ſharply toothletted. Petioles longer than the leaves. Stipules creſted, with long linear-ſetaceous ſegments, ſometimes toothed; the teeth ending in a briſtle. Peduncles almoſt the ſame length with the petioles, awned or ending in a long thread, one or ſometimes two-flowered[1]. Legumes ſolitary, orbicular, flatted, ſmooth, half an inch in diameter; with four or five turns of the ſcrew, which are leafy, horizontal, marked with radiant diſtant ſtreaks, toothleſs, many-celled, not opening. Seeds five to nine, roundiſh, turgidly lens-ſhaped, rufeſcent[2].

Native of the South of Europe. Ray obſerved it in Sicily.

β. Stems trailing, ſtriated, villoſe. Leaves on long petioles. Leaflets oval, very finely villoſe underneath, ſharply and unequally toothed. Stipules lanceolate, with fewer toothlets. Peduncles longer than the petioles, villoſe, awned, many-flowered. Flowers terminating, ſeſſile, pale yellow[3]. Legumes ſolitary or two together, ſometimes three, ſubglobular, making five, ſix or ſeven ſpiral turns, which are leafy-compreſſed, obliquely ſtriated, concave upwards, toothleſs or ſmooth, many-celled, not opening, dark brown when ripe. Seeds five or ſix, largiſh, kidney-form, deeply emarginate next the navel, of an orange-ruſeſcent colour[4].

Native of the South of France and Italy. Ray obſerved it near Leghorn.]

γ. This has trailing branches, and yellow flowers like the preceding, but the fruit is much longer and cloſer twiſted, reſembling a barrel or wine pipe, being leſs at each end than in the middle.

[According to Linnæus this has ſeveral ſubcylindric fruits, (two to ſix) with the turns of the ſcrew unarmed or ſmooth and flat, and toothed ſtipules.

Native of the South of France.

δ. According to Gerard, this is a variety of the preceding, with the legumes longer and leſs blunt. They are unarmed or ſmooth, as in the preceding, and ſubcylindrical, with the extremities flatted[5].

Native of the South of France.]

ε. The fruit of this is much larger than in the other varieties, and cloſely armed with long ſpines like a hedgehog, whence it had the Engliſh name; theſe ſpines point every way, ſo that it is very diſagreeable to handle.

[Stipules toothed. Legumes two or four, ovate or ovate-globular, with five compreſſed ſpires, concealed by awl-ſhaped, pungent, recurved prickles. Seeds five or more, largiſh, kidney-form, very dark cheſtnut-coloured, ſomewhat ſhining[6].

Native of the South of Europe.

ζ. Stems ſmooth, or with very few hairs, red. Leaves on very long petioles, glaucous and tomentoſe with a ſhort and ſcarcely conſpicuous nap beneath. Flowers axillary two or three together, ſmall, yellow. The leaves that firſt come out are heart-ſhaped; thoſe on the ſtem broad and blunt, beautifully ſtriated. Legumes oval, with ſhort, ſtiff ſpines, hard and larger than peas, becoming blackiſh when ripe. Seeds kidney-form, yellow[7]. According to Villars, the legumes make two turns and a half, each armed with a row of ſhort ſpines on both edges; they are ſmooth, though the leaves are villoſe.

Native of the South of France. Ray found it near Meſſina in Sicily, and at Orford in Suffolk, on the ſea bank, if that be the ſame, the ſpines on the legume being deſcribed as rather tender than ſtiff.

η. Stems numerous, a foot in length, more or leſs according to the ſoil, procumbent, four-cornered, with long whitiſh hairs below, but ſmooth above, ſtriated, purpliſh, branched. Petioles cylindrical, channelled, hairy in like manner. Leaflets obcordate, ſomewhat ribbed, ſmooth, obſcurely or partly ſerrate, marked above in the middle with a blackiſh brown or blood-coloured heart-ſhaped or ſagittate ſpot, varying in brightneſs, and according to Linnæus diſappearing after the plant has flowered. Stipules ſemi-ſagittate, acuminate, ſerrate. Flowers from two to four or five together, on axillary, round, hairy peduncles ſhorter than the leaves; when many, two or three are abortive: at the baſe of each pedunele a very ſmall braſte; and between the flowers a briſtle. Corolla yellow: banner emarginate, much larger than the other petals. Legume roundiſh-cylindrical, cut off at each end; the ſpires flat, with widely diverging prickles, hooked at the end[8].

This Medick is called by our Gerarde *Heart Trefoil*; others call it *Heart Clover* or *Clover*, corrupted by the vulgar into Heart Liver. Hudſon and Curtis name it *Heart Medick*; and Sibthorp, perhaps more ſignificantly, *Spotted Medick*.

It is common on banks and the borders of fields, in dry ſandy paſtures, and eſpecially near the ſea; flowering in may and june. It varies much in ſize.

In Hudſon's *hybrida* the peduncles are two-flowered or thereabouts. The lower legumes ſpiral, with five turns and diverging ſpines; the ſeeds perfect: the upper ones linear, half an inch long, bowed or curved inwards, ſlightly torulooſe or protuberant; ſeeds imperfect.

Found near Charlton in Kent. Mr. Curtis affirms that there is no Heart Medick near London but the common one.

ϑ. Leaves elliptic. Stipules ſcarcely toothed. Flowers in racemes, very ſmall[9]. Legumes ſubconical, with four, ſeparate, compreſſed turns, the outer ſuture marked with a raiſed line, and armed with ſhort ſubalternate ſpinules turning obliquely upwards and downwards. Seeds four or five, kidney-form, yellowiſh[10]. This variety, according to Gerard, is known by having ſeveral ſmaller legumes to each pedunele, with ſhorter almoſt erect ſpines, as Gouan remarks.

Native of the South of Europe.

ι. Stipules ciliate. Legumes ſeveral, oval, the ſpires or turns having ſtraighiſh villoſe ſpines[11].

Native of the South of Europe.

κ. Leaves ovate-lanceolate. Stipules entire. Peduncles many-flowered, forming a raceme. Legumes roundiſh, with ſix turns, ſpines hooked[12].—South of Europe.

λ. Peduncles many-flowered. Legumes compreſſed, with very ſtiff prickles.

Native of France.

μ. Root ſtriking deep, white, the ſize of ſmall twine, tough, with a few rigid fibres. Whole plant, except the flowers, covered with a white ſilky down. Stems ſomewhat angular, numerous, procumbent, often tinged with purple. Leaves petioled; outer leaflets ſeſſile, the middle one petioluled, oblong wedge-ſhaped, entire at the baſe, ſerrated towards the top, marked with ſtrong nerves, the terminations of which form the ſerratures; the end emarginate with an intermediate projecting point. Stipules lanceolate, entire, nerved. Peduncles as long as the leaves, bearing from one to ſix flowers, in a looſe head, on ſhort unequal pedicels. Teeth of the calyx awl-ſhaped, equal. Corolla ſmall, pale yellow. Legumes ſcarcely larger than the ſeeds of Ornbus; the ſpires covered with rigid hooked prickles[13].

Native of ſeveral parts of Europe. In England on ſandy ſoils, but rare. Found by Mr. Woodward at Narborough near Swaffham in Norfolk.

ν. Peduncles few-flowered. Legumes black, ſpiral, with hooked prickles the length of the legumes.

Native of the South of France[14].]

ξ. Stems trailing. Leaflets wedge-ſhaped, ſharply toothed, with three acute points at the top. Flowers pale yellow. Fruit ſmall, with many weak ſpines.

[The leaves, according to Linnæus, are like thoſe of Trigonella laciniata, and appear as if gnawn at the

edge by inſects. Leaflets oblong, emarginate, and pilloſe with two longer teeth on each ſide. Pedunclesawned, ſuſtaining about two flowers, and ſhorter than the leaves.

Native of Syria, about Aleppo.

There are other varieties mentioned by Gærtner, Retzius, and others, but the above will probably be deemed ſufficient. Some of them have been long cultivated in our gardens, but are not ſo much regarded at preſent as they were heretofore.

11. This is a very ſmall plant, with a ſmall fruit. It is nearly allied to M. polymorpha, but is perennial.

Its native place is not known.]

PROPAGATION AND CULTURE.

1. The Medick may be propagated by ſowing the ſeeds upon a moderate hot-bed, or a warm border of light earth, in the beginning of april; and when the plants come up, they ſhould be carefully cleared from weeds; but they ſhould remain undiſturbed, if ſown in the common ground, till ſeptember following; but if on a hot-bed, they ſhould be tranſplanted about midſummer into pots, placing them in the ſhade until they have taken root; after which they may be removed into a ſituation where they may be ſcreened from ſtrong winds, in which they may abide till the end of october, when they muſt be put into a common garden frame, to ſhelter them from hard froſts; for thoſe plants which have been brought up tenderly, will be liable to ſuffer by hard weather, eſpecially while they are young. In april following theſe plants may be ſhaken out of the pots, and placed in the full ground where they are deſigned to remain, which ſhould be in a light ſoil and a warm ſituation, in which they will endure the cold of our ordinary winters extremely well, and continue to produce flowers moſt part of the year, and retaining their leaves all the winter renders them the more valuable.

Thoſe alſo which were ſown in an open border may be tranſplanted in auguſt following, in the ſame manner, but in doing this be careful to take them up with a ball of earth to their roots, if poſſible, as alſo to water and ſhade them until they have taken root; after which they will require little more care than to keep them clean from weeds, and to prune off the luxuriant branches to keep them within the compaſs; but never prune them early in the ſpring, nor late in autumn, for if froſt ſhould happen ſoon after they are pruned, it will deſtroy the tender branches, and many times the whole plant is loſt thereby.

Theſe plants have been formerly preſerved in the green-houſe, ſuppoſing them too tender to live through the winter in the open air; but I have had large plants of this kind, which have remained in a warm ſituation many years without any cover, and have been much ſtronger, and flowered better than thoſe which were houſed; though, indeed, it will be proper to keep a plant or two in ſhelter, leſt by a very ſevere winter (which ſometimes happens in England) the plants abroad ſhould be deſtroyed.

They may alſo be propagated by cuttings, which ſhould be planted in april, upon a bed of light earth, and watered and ſhaded until they have taken root, after which they may be expoſed to the open air; but they ſhould remain in the ſame bed till july or auguſt following, before they are tranſplanted, by which time they will have made ſtrong roots, and may be removed with safety to the places where they are to remain, obſerving (as was before directed) to water and ſhade them until they have taken root; after which you may train them up with ſtraight ſtems, by faſtening them to ſticks, otherwiſe they are apt to grow crooked and irregular; and when you have got their ſtems to the height you deſign them, they may then be reduced to regular heads, and with pruning their irregular ſhoots every year, they may be kept in very good order.

3, 4, 5. Theſe annual ſorts are preſerved in the gardens of thoſe who are curious in botany; the ſeeds ſhould be ſown upon an open bed of freſh ground, in the places where the plants are to remain, becauſe they do not bear tranſplanting well, unleſs when they are very young. As the plants ſpread their branches on the ground, they ſhould not be ſown nearer than two feet and a half aſunder; when the plants come up, they will require no other care but to keep them clean from weeds. In june they will begin to flower, and as the ſtalks and branches extend, there will be a ſucceſſion of flowers produced till the autumn; but the early flowers are ſuch as will have good ſeeds ſucceed them, for thoſe which come late in ſummer, have not time to ripen before the cold weather comes on.

6. Lucern. This valuable plant will bear the heat of ſuch climates as the Spaniſh Weſt Indies, where it is ſown in all the plains round Lima, and furniſhes green fodder for their cattle all the year round, and may be cut every week. It would probably be of great ſervice therefore in our Weſt Indian iſlands. It is commonly cultivated along the banks of the Rhone, and in many other parts of the South of Europe, where it may be cut five or ſix times in a year. But it alſo bears our climate very well, and may be cut four or five times in a ſeaſon between the middle of april and november.

The directions given by former writers are imperfect and erroneous. Many order it to be ſown with oats or barley, as is practiſed for Clover; but in this way it ſeldom comes up well, or draws up ſo weak as not to recover itſelf under a whole year. Others have directed it to be ſown upon a low, rich moiſt ſoil, which is found to be the worſt next to a clay, of any for this plant; in both which the roots will rot in winter, and in a year or two the whole crop will be deſtroyed.

But the ſoil in which this plant is found to ſucceed beſt in this country is, a light, dry, looſe, loamy or ſandy land, which ſhould be well ploughed and dreſſed, and the roots of all noxious weeds, ſuch as Couch Graſs, &c. deſtroyed, otherwiſe they will overgrow the plants, while young, and prevent their progreſs.

The beſt time to ſow the ſeed is about the middle of april, when the weather is ſettled and fair; for if you ſow it when the ground is very wet, or in a rainy ſeaſon, the ſeeds will burſt and come to little (as is often the caſe with ſeveral ſorts of the leguminous plants,) therefore you ſhould always obſerve to ſow it in a dry ſeaſon, and if there happens rain in about a week or ten days after it is ſown, the plants will ſoon appear above ground.

But the method I would direct for the ſowing theſe ſeeds is as follows; after having well ploughed and harrowed the land very fine, you ſhould make a drill quite acroſs the ground, about half an inch deep, into which the ſeeds ſhould be ſcattered very thin by a hopper fixed to a drill plough; then cover them over half an inch thick, with the earth that came out of the drill; then proceed to make another drill about two feet and a half from the former, ſowing the ſeeds therein in the ſame manner as before, and ſo proceed through the whole ſpot of ground, allowing the ſame diſtance between row and row, and ſcatter the ſeeds very thin in the drills. In this manner, an acre of land will require about ſix pounds of ſeeds; for when it is ſown thicker, if the ſeed grows well, the plants will be ſo cloſe as to ſpoil each other in a year or two, the heads of them growing to a conſiderable ſize, as will alſo the roots, provided they have room. I have meaſured the crown of one root, which was in my poſſeſſion, eighteen inches diameter; from which I cut near four hundred ſhoots at one time, which is an extraordinary increaſe, and this upon a poor, dry, gravelly ſoil, which had not been dunged for many years, but the root was at leaſt fourteen years old; ſo that if this crop be well cultivated, it will continue many years, and be equally good as when it was firſt ſown; for the roots generally run down very deep in the ground, provided the ſoil be dry; and although they ſhould meet a hard gravel a foot below the ſurface, yet their roots would penetrate it, and make their way downward, as I have experienced, having taken up ſome of them which were above four feet in length, and had run above two feet into a rock of gravel, which

[a] Linn.

which was ſo hard as not to be looſened without mattocks and crows of iron, and that with much difficulty.

The reaſon for directing this ſeed to be ſown in rows is, that the plants may have room to grow; and for the better ſtirring the ground between them, to deſtroy the weeds, and encourage the growth of the plants, which may be very eaſily effected with a Dutch hoe, juſt after the cutting the crop each time, which will cauſe the plants to ſhoot again in a very little time, and be much ſtronger than in ſuch places where the ground cannot be ſtirred; but when the plants firſt come up, the ground between them ſhould be hoed by hand with a common hoe; and if in doing this you cut up the plants where they are too cloſe in the rows, it will cauſe the remaining to be much ſtronger. This hoeing ſhould be repeated two or three times while the plants are young, according as the weeds are produced, obſerving always to do it in dry weather, that the weeds may the better be deſtroyed; for if it be done in moiſt weather, they will take root and grow again.

With this management, the plants will grow to the height of two feet, or more, by the beginning of auguſt, when the flowers will begin to appear, when it ſhould be cut for the firſt time, obſerving to do it in a dry ſeaſon, eſpecially if it is to be made into hay, and keep it often turned, that it may ſoon dry, and be carried off the ground; for if it lie long upon the roots, it will prevent their ſhooting again. After the crop is taken off, you ſhould ſtir the ground between the rows with a hoe, to kill the weeds, and looſen the ſurface, which will cauſe the plants to ſhoot again in a ſhort time, ſo that by the middle of ſeptember there will be ſhoots four or five inches high, when you may turn in ſheep upon it to feed it down, for it will not be fit to cut again the ſame ſeaſon; nor ſhould the ſhoots be ſuffered to remain upon the plants, which would decay when the froſty weather comes on, and fall down upon the roots, and prevent their ſhooting early the ſucceeding ſpring; but theſe ſheep ſhould not remain ſo long upon it as to endanger the crowns of the roots.

So that the beſt way is to feed it until november, when it will have done ſhooting for that ſeaſon; but it ſhould not be fed by large cattle the firſt year, becauſe the roots being young, would be in danger of being deſtroyed, either by their trampling upon them, or their pulling them out of the ground; but ſheep will be of ſervice to the roots by dunging the ground, provided they do not eat too cloſe.

The beginning of february, the ground between the roots ſhould be again ſtirred with the hoe, to encourage them to ſhoot again; but in doing this be careful not to injure the crown of the roots, upon which the buds are at that time very turgid, and ready to puſh. With this management, if the ſoil be warm, by the middle of march the ſhoots will be five or ſix inches high, when, if you are in want of fodder, you may feed it down till a week in april; after which it ſhould be ſuffered to grow for a crop, which will be fit to cut the beginning of june, when you ſhould obſerve to get it off the ground as ſoon as poſſible, and ſtir the ground again with a Dutch hoe, which will forward the plants ſhooting again, ſo that by the middle of july, there will be another crop fit to cut, which muſt be managed as before; after which it ſhould be fed down again in autumn, and as the roots by this time will have taken deep hold in the ground, there will be little danger of hurting them, if you ſhould turn in large cattle; but you muſt always obſerve not to ſuffer them to remain after the roots have done ſhooting, leſt they ſhould eat down the crown of the roots below the buds, which would conſiderably damage, if not deſtroy them. In this manner you may continue conſtantly to have two crops to cut, and two feedings upon this plant, and in good ſummers there may be three crops cut, and two feedings; which will be a great improvement, eſpecially as this plant will grow upon dry barren ſoils, where Graſs will produce little, eſpecially in dry ſeaſons, when it will be of great uſe, the Graſs being often burnt up. And as it is an early plant in the ſpring, ſo it will be of great ſervice when fodder falls ſhort at that ſeaſon, when it will be fit to feed at leaſt a month before Graſs or Clover; for I have had this plant eight inches high by the tenth of march, old ſtyle, at which time the Graſs in the ſame place has ſcarcely been one inch high.

That the cold will not injure this plant, I am fully ſatisfied; for in the very cold winter, anno 1729-30, I had ſome roots of this plant which were dug up in october, and laid upon the ground in the open air till the beginning of march, when I planted them again, and they ſhot out very vigorouſly ſoon after; nay, even while they lay upon the ground, they ſtruck out fibres from the under ſide of the roots, and began to make ſhoots from the crown of the roots. But that wet will deſtroy the roots I am fully convinced, for I ſowed above an acre upon a moiſt ſpot of ground for a trial, which came up very well, and flouriſhed exceedingly during the ſummer ſeaſon, but in winter, when the great rains fell, the roots began to rot at bottom, and before the ſpring moſt of them were deſtroyed. There has been lately ſome perſons who have adviſed the ſowing of Lucern in broad-caſt, and to make uſe of a ſtrong harrow, to tear up and deſtroy the weeds which naturally grow up among the plants; but this advice has been given too prematurely, therefore it is to be hoped will not be followed by any diſcreet perſons, who are deſired to take a ſurvey of ſome of theſe lands which have been ſo cultivated three or four years, which I am fully perſuaded will convince them of the bad huſbandry, for no perſon who has any regard neatneſs and utility, will ever practiſe this method.

The beſt places to procure the ſeed from, are Switzerland, and the northern parts of France, for the ſeeds ſaved in thoſe countries ſucceed better with us than that which comes from a more ſouthern climate; but this ſeed may be ſaved full as well in England, and in as great plenty, were people curious enough to let the firſt crop ſtand for that purpoſe; in order to which, a ſmall quantity of the plants ſhould be ſuffered to grow uncut till the ſeeds are ripe, which is commonly about the beginning of ſeptember, when it muſt be cut, and laid to dry in an open barn, where the air may freely paſs through, but be defended from the wet; for if it be expoſed thereto, it will ſhoot while it remains in the pod, whereby it will be ſpoiled. When it is quite dry, it muſt be threſhed out, and cleanſed from the huſk, and preſerved in a dry place till the ſeaſon for ſowing it; and this ſeed ſaved in England is much preferable to any brought from abroad, as I have ſeveral times experienced, the plants produced from it having been much ſtronger than thoſe produced from French, Helvetian, and Turkey ſeeds, which were ſown at the ſame time, and on the ſame ſoil and ſituation.

I am inclinable to think, that the reaſon of this plant not ſucceeding, when it has been ſown in England, has either been occaſioned by the ſowing it with Corn, with which it will by no means thrive, (for though the plant be very hardy when grown pretty large, yet at its firſt coming up, if it be incommoded by any other plants or weeds, it ſeldom does well; therefore it ſhould always be ſown by itſelf, and carefully cleared from weeds until it has ſtrength, after which it is not eaſily deſtroyed;) or, perhaps, people have ſown it at a wrong ſeaſon, or in wet weather, whereby the ſeeds have rotted, and never come up, which has diſcouraged their attempting it again: but however the ſucceſs has been, I dare aver, that if the method of ſowing and managing this plant, which is here laid down, be duly followed, it will be found to thrive as well as any other ſort of plant now cultivated in England, producing a much greater crop than any other ſort of fodder, and will continue much longer; for if the ground be duly ſtirred after the cutting each crop, and the laſt crop fed as has been directed, the plants will continue in vigour forty years or more, without renewing, provided they are not permitted to ſeed, which will weaken the roots more than four times cutting it would do. The hay of this plant ſhould be kept in cloſe barns, it being too tender

to

to be kept in ricks open to the air as other hay; but it will remain good, if well dried before it be carried in, three years. The people abroad reckon an acre of this fodder sufficient to keep three horses all the year round.

And I have been assured by persons of undoubted credit, who have cultivated this plant in England, that three acres of it had fed ten cart-horses from the end of april to the beginning of october, without any other food, though they have been constantly worked. Indeed, the best use which can be made of this Grass is, to cut it, and give it green to the cattle; where this has been daily practised, I have observed that by the time the field has been cut over, that part which was the first cut has been ready to cut again; so that there has been a constant supply in the same field, from the middle of april to the end of october: when the season has continued long mild, and when the summers have proved showery, I have known six crops cut in one season, but in the driest seasons there will be always three or four. When the plant begins to flower, it should then be cut; for if it stands longer, the stalks will grow hard, and the under leaves will decay, so that the cattle will not so greedily devour it. Where there is a quantity of this cultivated, some of it should be cut before the flowers appear, otherwise there will be too much to cut within a proper time.

When this is made into hay, it will require a great deal of making; for as the stalks are very succulent, it must be often turned, and exposed a fortnight or longer, before it will be fit to house; for this requires a longer time to make than Saint Foin; therefore, when it is cut, it should be carried to make upon some Grass ground, because the earth in the intervals of the rows will wash up, and mix with the hay in every shower of rain, and by carrying it off as soon as it is cut, the plants will shoot up again soon; but it is not so profitable for hay, as to cut green for all sorts of cattle, but especially horses, which are extremely fond of it; and to them it will answer the purpose both of hay and Corn, and they may be worked at the same time just as much as when they are fed with Corn, or dry food.

To these directions of Mr. Miller may be added the result of more modern experience.

John Pratt Esq. of Poorfleet in Essex sowed Lucern in a field of good hazle loam, neither too light nor too stiff, the soil about three feet deep, with a chalky bottom.

The field in 1773 had borne turneps, properly hoed and fed off with sheep; and on april 13th 1774, after the land had two ploughings and harrowings, the ground being fine, he began to sow in drills twenty inches distant on two acres, six pounds of seed on an acre, covering it with a garden rake.

In may and june the fly (flea) made great havock, so that at different times the sowing and hoeing were repeated until the 5th of july, when the rows were complete, and those parts that were not damaged by the fly were in a thriving state. On the 30th of july he began to cut, and by the 20th of september, it it had been cut all over once. At the end of october he laid ten loads of rotten dung on each acre, and with a small plough turned the earth each way out of the alleys over the plants, so that the land appeared like a fallow.

In this state it lay until the 20th of february, when it was bush-harrowed cross-wise, to lay the ridges down into the alleys again.

On the 27th of may he began to cut, the Lucern being about twenty inches high.

June the 20th he began to cut a second time, and followed this cutting with a horse-hoeing in the alleys, and hand-weeding in the rows. August the 7th he began to cut the third time. September the 26th the fourth time. And november the 6th dunged and ploughed as in the preceding year.

In 1776, the weather being wet, he could not bush-harrow until the 12th of march; and on the 27th the plants growing fast, he gave it a perfect hand-weeding in the rows. He began cutting in may, and during this summer cut four crops, horse-hoing the alleys each time. In september he hand-weeded again, and in november dunged and ploughed the alleys as before.

In may this year he sowed near two acres more, adjoining to the above piece, which land had the preceding winter borne cabbages, which were taken off before Christmas, and the land was then ploughed and prepared for sowing. The plants came up well, and no accident happened from the fly. He cut this sowing once, and cultivated it in the same manner as the other.

In 1777, february the 28th he levelled the ridges with a bush-harrow. May the 22nd he began to cut, and had four crops again this summer, horse-hoeing after each cutting. He hand-weeded the rows in october; and in november dunged and ploughed the alleys as before.

This year he added seven rows, to make the quantity four acres.

1778, in february, harrowed down as before. May the 4th began cutting, and had four crops as usual. The last cutting was finished the 30th of october, when the land was treated as in the former years.

This year the four acres kept eleven horses from the 4th of may to the 31st of october, and they improved much with only half their usual allowance of corn. Three additional horses were likewise fed from this Lucern seventy-four days.

1779, in february bush-harrowed as usual. May the 7th begun to cut, and fed ten horses: on the 21st added two horses; but before the whole was cut, the part where the cutting commenced had grown so luxuriantly as to be in flower; twenty-one horses therefore were added during seven days, before he began to cut the second time, which was on june the 24th. He began to cut the third time on august the 3rd; and the fourth time on september the 9th.

The plants continued growing in such a manner, that by the time the whole four acres had been cut over, which was on the 10th of october, the part first cut was grown twelve inches high. It being then too late in the season for another cutting, fifteen head of horned cattle were turned in for eight days. He then gave it a hand-weeding, and dunged and ploughed as before.

The produce this year maintained ten horses twenty-two weeks; two horses twenty weeks; twenty-one horses one week; and fifteen head of cattle eight days.

Mr. Pratt remarks, that the land which bore cabbages, was preferable to that which had turneps, being much cleaner.

That may is the proper month for sowing; that hand-hoeing and weeding are requisite the first year, the plants being then too tender for the horse-hoe; and that cutting once only the first year, gives the roots time to shoot down and gather strength.

That horse-hoeing the alleys after every cutting, and hand-weeding the rows in march or april are necessary; and before it is laid up for the winter, should not on any account be omitted. After the last cutting and weeding, he recommends ten or twelve loads of rotten dung to be laid on an acre, and gathered up with a small plough, to form the ridges over the crowns of the roots. In february, the first dry day, these ridges are to be bush-harrowed down into the alleys.

This is a principal feature in Mr. Pratt's culture of Lucern. Mr. Belcher affirms that Mr. Miller could not have had any experience in Lucern, because he does not recommend this practice; and yet Mr. Young asserts from his own knowledge, that so far from doing good, it injures the crop.

The third year, as Mr. Pratt proceeds to observe, the plants appear to arrive at their perfection, neither improving nor diminishing afterwards.

Neither dry nor wet weather materially affects its growth, which is about an inch a day; but something less, if the weather be cold.

Lucern has the effect of salt-marshes, it purges and is diuretic for three or four days, and then fattens horses at a great rate, with scarcely half the usual allowance of corn.

Sheep will scoop the crowns of the roots, and thus deſtroy the buds formed for the ſucceeding ſhoot, they ſhould not therefore be permitted to bait on it: but this is not the caſe with horned cattle.

The drills of the firſt two acres were made by a line and hoe; but thoſe of the laſt two acres were made by taking out the teeth of a horſe-rake, and fixing in ſome angular teeth, like the angular chiſſel of the wheelers, at twenty inches diſtance, which performed the work well. The laſt were done at half the expenſe[3].

A Gentleman Farmer in Hertfordſhire divided a field of two acres into four parts, and ſowed it with Lucern, the firſt part in drills three feet aſunder, the ſecond two feet, the third one foot, and the fourth broad-caſt. The ſoil was equal throughout the field. The ſeed was ſown on the 24th of april, and the crop was cut on the 16th of auguſt.

This year the plants in every part of the field were nearly equal in goodneſs, but the number being much greater on an equal ſpace of ground in the part ſown broad-caſt, the crop was of courſe heavieſt there; theſe plants being as good the firſt year as afterwards. But in the courſe of three years, the plants in the three-feet drills became much ſtronger, and ſpread ſo as nearly to fill up the intervals. The produce of one root was then more than that of any ten roots in the broad-caſt part; which by ſtanding too cloſe were impoveriſhed, and could not increaſe in bulk like the others.

In the fourth year the produce of the three-feet drills was more than double the broad-caſt; this land alſo was kept free from weeds by the horſe-hoe, and was earthed up at a ſmall expenſe. At the end of this year, the broad-caſt part was ploughed up, and planted afreſh with roots from the one-foot drills, in three-feet rows. The firſt ſeaſon they ſeemed ſtunted, but the following ſpring they ſhot forth vigorouſly, and were nearly equal to the other.

Weeds are the greateſt enemies to Lucern: the eaſieſt and cheapeſt way of keeping the crop clean, is to ſow it in drills of ſufficient width to admit the horſe-hoe; which not only deſtroys the weeds at the leaſt expenſe, but greatly promotes the growth of the plants, by earthing them up in the operation[4].

Mr. Baldwin of Clapham ſowed a field of four acres and a half with Lucern. The ſoil a ſandy dark-coloured loam, good turnep land, and yielding good barley. Two acres were tranſplanted in ſeptember 1764. An acre was drilled by hand the 2nd of may 1765; the rows in both two feet aſunder. The tranſplanted was firſt hoed in november 1764, and coſt 6s. an acre: it was hoed again in april following at 10s. an acre. Weeding by hand the drilled acre the middle of june following coſt 12s. an acre. The ſummer of 1765 being very dry, the produce was very trifling.

In 1766 Mr. Baldwin began to cut it the 28th of april, when it ſerved his horſes and cows to the 7th of june, ſix weeks. On the 7th of july he cut the whole three acres for hay, about three loads; and about three loads more on the 15th of auguſt: the fourth crop, which was pretty good, he fed off with cows and ſome ſheep.

In 1767 he began to cut it on the 11th of may, and fed five horſes, with four cows occaſionally, till the 20th of june, ſix weeks; when he mowed the remainder, being about an acre, and it yielded a load and half of hay.

He weighed the crop at different periods, and found on the 30th of may, one rod of drilled Lucern to weigh 95lbs. On the 9th of june, one rod of tranſplanted weighed 80lb; and on the 20th of the ſame month a rod of the tranſplanted weighed 120lb. On the ſame day a rod of broad-caſt Lucern belonging to a neighbouring gentleman, with ſome graſs and weeds weighed 158lb.

Some gentlemen and jobbing coachmen in his neighbourhood being deſirous of feeding their horſes with Lucern, Mr. Baldwin agreed to do it for them at the ſame price they gave for tares, that is 7d. a bundle of 60lb, or 6s. a week for every horſe. Hence he diſcovered that one rod with another the ſecond crop yielded from 60 to 64lbs; that a large coach-horſe would eat about 90lb in twenty-four hours, and that an acre would ſerve five horſes twenty-one days.

Cleaning Lucern in rows by hand-hoeing being much too expenſive, Mr. Baldwin invented a horſe-hoe, with which he cleaned his field very well at the end of october in two days, with one man, a horſe and a boy; by this means he reduced the heavy expenſe of hoeing to 1s. 6d. or 2s. an acre. He alſo invented a hoeing plough, with which on the 17th of november he ploughed his three acres five or ſix inches deep; afterwards harrowing the field acroſs with common harrows, and carting off near eight loads of weeds. Thus it lay till he began to cut it on the 11th of may, horſe-hoeing as he went on once a week, and alſo after every cutting. Drawing the drills, ſowing the ſeed by hand, and covering it by two boys at 3s. a day, and two men at 2od. coſt for an acre about 10s. Raiſing the plants, ploughing, and planting the tranſplanted Lucern coſt about 30s. an acre.

Mr. Baldwin obſerving that Lucern the firſt year yielded but little, on an acre and half ſowed three buſhels of barley on the 30th of march; and on the 8th 9th and 10th of april drilled it with Lucern[5].

Soil.

As to the ſoil, Virgil is always quoted to ſhow that ſuch as is looſe and crumbling, or rich and putrid, is moſt proper for Lucern. Even the learned Harte has fallen into this error. But Virgil's precept relates not to the ſoil, but to the management of it, which is of much greater conſequence, becauſe that is more in our power. He does not recommend a rich putrid ſoil preferably to all others, but that the land ſhould be well pulverized by ploughing, &c. ſo as to be in a proper condition to receive the ſeed.

——Tu quoque Media putres
Accipiunt *ſulci*.

It is remarkable that Harte changes *putres ſulci* into *putri terra*, makes it ſynonymous with the *temperata* of Varro, and tranſlates it a rich loamy earth.

This is certainly an excellent ſoil for Lucern, or indeed for any thing elſe, when it can be had, but not being the moſt common, we muſt frequently be contented with ſuch ſoils as are worſe. Rocque ſays that the ſtrongeſt is to be preferred; and Mr. Beleher, that although it will ſucceed on moſt middling ſorts of land, it ſhould, if poſſible, have a ſoil both ſtiff and dry, or as he elſewhere ſays, ſuch as is cloſe, firm, and ſound, in oppoſition to the foreign writers, with Tull and Miller, who recommend a light, looſe, ſandy ſoil. The right ſoils, according to others, are deep rich friable loams, whether ſandy or gravelly, or flexible loams, &c. deep and rich; in a word, all rich ſoils that are dry. In Kent it is ſown in dry lands. Under the South Downs of Suſſex, in the vicinity of Eaſt Bourn, where Lucern is a common article of cultivation, they rarely ſow it upon any but the richeſt and deepeſt ſoils, thinking that it does not anſwer on any other. Their land is ſuch a happy mixture of the calcareous and argillaceous, and is of ſo deep a ſtaple, that any thing will grow upon it, and Lucern, Sainfoin and Clover may be found ſide by ſide. I have however ſeen very good crops of Lucern produced in gravelly, ſandy and ſtony loams, by no means rich, and even on poor ſandy gravel, apt to burn. One of the beſt crops I was ever witneſs to was on brick and lime rubbiſh, the remains of old buildings. I never ſaw it proſper on very ſtiff clays, nor on wet ſpringy lands, nor on any ſoil very retentive of moiſture. It has a better chance even on thin loams on rock and on poor ſands, though no man would chooſe ſuch ſoils for it, if he had better, becauſe the roots of Lucern will travel far in ſearch of nutriment.

Preparation.

The great buſineſs in the culture of Lucern being to keep it free from weeds, eſpecially whilſt it is young, much depends upon preparing the ſoil in ſuch a manner

[3] Tranſ. Soc. Arts. vol. 1. [4] Bath papers, vol. 2. 104. [5] Young's 6x weeks tour, 220.

that all ſorts of uſeleſs plants ſhall be killed. It is much cheaper to prevent weeds than to deſtroy them, and every ſhilling laid out in cleaning the land, will ſave a crown in hoeing the crop. For this reaſon two ſucceſſive crops of turneps or carrots prepare the land well for it: but as turneps upon good loams, if carted in a wet ſeaſon, are apt to prevent that friability which is neceſſary for Lucern, the turneps ſhould be fed off in autumn, and the land immediately ploughed. Carrots are not liable to any objection, for they ſhould always be drawn and laid up before winter, and the inceſſant hoeing which they require, cleans the land admirably. If the land be prepared by a fallow, let a man with a baſket and four-pronged fork follow the plough in every furrow, and the harrows whenever they work, to pick up all roots and weeds, and to clear away ſuch knots and tufts as the plough does not go deep enough to eradicate. Carrots, turneps or cabbages may be made preparatory crops; at leaſt there ſhould be two hoeing crops in ſucceſſion. In the ſecond ſpring, previous to the ſowing, there ſhould be three ploughings, and harrowings enough to pulverize the ſoil well. Thus we ſhall attain the *putres ſulci* or crumbling furrows of Virgil[1].

Rocque recommends peas and beans as a good preparation, or potatoes as the beſt: the next ſeaſon a fallow for turneps, to be fed off with ſheep. Or forward peas, and turneps as ſoon as they are off, to be fed by Chriſtmas, then trench-ploughed, and the Lucern ſown in april. In Kent the common tillage is a good ſummer fallow, ploughed as deep as poſſible, with a good covering of manure.

According to Mr. Wynn Baker turneps are the beſt preparation. A. St. Leger, Eſq; prepared ſucceſsfully by paring and burning. But whether the preparation be by hoeing crops, &c. or by a fallow, it is indiſpenſable that the land ſhould be well pulverized by plough and harrow, laid as flat as poſſible, and cleared of all weeds. If it be on a deſcent, and not dry, the furrows ſhould be drawn down the land; but if the ſoil be very dry, they had better be across it. If the land be in heart, there is no occaſion for any manure; or if manure be applied, it ſhould be with the firſt of the two hoeing crops. Mr. Rocque recommends freſh ſtable dung to be laid on before the laſt ploughing, and to be ploughed in directly; but this will be apt to fill the land with weeds, and cannot be neceſſary if it was manured for the firſt hoeing crop.

Modes of Sowing. 1. *Broad-caſt.* 2. *Drilling.*

Both modes have ſucceeded with different perſons, and both have failed. Circumſtances muſt govern the deciſion of the cultivator. If he be doubtful whether he ſhall be able to give a regular and conſtant attention to hand and horſe-hoeing, or if he be ſatisfied with his crop laſting eight or ten years, then the broad-caſt may be preferred. But if he be willing and able to have the crop perfectly well managed in reſpect to hoeing, and if he be deſirous to have it laſt twenty or thirty years, he will then probably prefer the drill culture. Both have their advantages and diſadvantages.

Time of Sowing.

Whichever method be adopted, the time of ſowing is chiefly during the month of april. The end of march is commonly too early: and the chance of a failure is greater in may than in april, both on account of the drought and the fly. It ſhould be ſown later on heavy than on light lands; and if poſſible in dry weather, when there is a proſpect of ſhowers.

Columella directs it to be ſown at the end of april, and it is remarkable that Pliny ſays it is ſown in may, becauſe it ſown earlier it would be liable to injury from white froſts. If this be the caſe in Italy, how imprudent, it will be ſaid, muſt it be, to ſow here in april. Yet in practice I have ſcarcely ever known april-ſown Lucern receive any material injury from froſt.

Quantity of Seed.

In ſowing broad-caſt Rocque directs 12lb to an acre; in Kent they ſow from 16 to 20lb; near Eaſt Bourn they ſow 20lb, which is generally allowed to be the proper quantity: in France they allow near 30lb to an Engliſh acre. Some ſow only 10lb, with 6lb of broad clover, to have a crop the firſt ſeaſon, both with a thin crop of barley or oats. Where Lucern is put in broad-caſt alone, it ſhould not be too thin, becauſe the method of cleaning it is ſo ſevere that the crop might be reduced too much whilſt it is young and tender[m].

In drilling 6lb. of ſeed is by ſome thought ſufficient to ſow an acre in two-feet rows. In this proportion about 8lb will be required for eighteen inch rows, 12lb for twelve inch rows, and 18lb. for nine inch rows[n]. Mr. Belcher however directs 12lb, or about a gallon and half of ſeed to be ſown on an acre, when the rows are two feet aſunder[o].

Diſtance of Rows.

In the Drill culture of Lucern there is much difference of opinion reſpecting the beſt diſtance for the rows, and directions are given for diſtances from nine to forty inches. Thoſe who approximate to the broad-caſt culture are for the former, and ſtill prefer it to that, becauſe it will admit a good furrow with a narrow ſhare inſtead of the broad-caſt harrowing. But the advocates for the horſe-hoeing culture prefer greater diſtances. Mr. Miller and Mr. Belcher recommend two feet. Mr. Harte ſtands almoſt alone for forty inches. Two-feet rows will admit of horſe-hoeing; and Lucern cannot be kept clean without it, except at too great an expenſe.

Some reſpect ſhould be had to the quality of the land. The rows may be cloſer on land that is leſs rich. Thus ſome recommend one-foot rows on ſoils worth 30s. an acre, and nine-inch rows on thoſe which are worth only 20s: reputing ſoils of leſs value as in general not much to be recommended for Lucern[p].

Sowing with or without Corn, &c.

Mr. Miller was a decided enemy to ſowing this or any other leguminous crop with corn. Others however are advocates for this mixture. Barley is moſt commonly uſed for this purpoſe, not more than one or two buſhels to the acre; Sprat-Barley is better than the common, as leſs liable to lodge: but perhaps Oats ſhould be preferred, two buſhels to the acre, as being ſtill leſs apt to lodge when ſown thin. This is practiſed in Flanders, and a few pounds of Clover ſeed are added. If the land is very rich, ſix pecks an acre may be enough; but if not, two buſhels ſhould be ſown, and upon poorer land three. In Kent they ſow it with a thin crop of Barley. After the corn is ſown and harrowed, ſow the Lucern, and finiſh with a light harrow[q]. The corn ſhould be mown green and given to cattle[r]. Some have tried Beans, and others Peas with the Lucern inſtead of Corn[s].

Broad-caſt culture.

If the Lucern be ſown with corn, and that be ſuffered to ſtand for a crop, as ſoon as harveſt is over, nothing is to be done to it but keeping cattle out, or the ſtubble ſhould be fed only by calves and young cattle, and that in dry weather. Rocque directs it to be harrowed when one year old with a large harrow, in dry weather, early in the ſpring to kill the weeds, and to dreſs it with rotten dung. Others delay this operation till after the ſecond cutting of the Lucern. Some caution ſhould be obſerved not to harrow ſo ſeverely as may be done afterwards. The ſecond ſpring Rocque directs to plough the ground with a drill plough without a coulter. Pliny ſays, that if weeds get ahead, the only remedy is frequent ploughing, till all other roots be deſtroyed. Tull gives a remarkable inſtance of a plant mangled by the plough for twenty-two years, and yet thriving. This plant therefore, when it has acquired ſtrength, for it is very delicate at firſt, will bear the action of the plough, at leaſt with a round ſhare; or harrowing twice in a ſeaſon, in may or june, and auguſt or ſeptember, with a heavy harrow. The weeds ſhould be collected and carried off, and then it may be levelled for the ſcythe with a barley roller. Half a growth in autumn, inſtead of being mown,

[s] Id. 3. 433.

may be fed off with cattle. Before every harrowing, if there be any thin places, ſome ſeed may be ſcattered into them[1].

I do not ſee why in ſowing Lucern broad-caſt, the plants may not be ſingled out and kept clean with the hand-hoe, in the ſame manner with turneps[2].

Mr. Belcher ſays, that the beſt way to meliorate broad-caſt Lucern is in autumn to ſtrike the ground up into ſharp ridges with a pointed ſhare, that the plants may be injured as little as poſſible. Then in the ſpring to plough it without a coulter croſſwiſe, with a pointed ſhare, or only ſtruck; and afterwards to harrow it down. When the Lucern ſhoots, if there be any vacant ſpots, ſow afreſh, and rake the ſeed in. When the ground is mellow, the autumnal ſtrike-baulking, as it is termed in Kent, will not much injure the Lucern, which having ſtringy tough roots, the pointed ſhare ſlips by them. But all the plants will not be ſo equally covered in this culture as in drills, over which each ridge may be centered. The ſnake-headed harrow would, if any, tear out the graſs from broad-caſt crops, without the uſe of the plough: the time to uſe it would be in winter and wet weather. If the vacancies are neglected in april, they may be ſown after the firſt cutting[3].

Dr. Tanner of Hadleigh in Suffolk had four acres ſown broad-caſt. The crop was four years old when Mr. Young examined it. He found it on a medium twenty-five inches high, thick and luxuriant, but far from being free of weeds. It had been harrowed in Mr. Rocque's manner, with a heavy harrow every year in march; which was thought to be of great ſervice in looſening the ground, though not in deſtroying the weeds altogether. Theſe four acres are the chief ſupport of fourteen or fifteen horſes and cows from the end of april till Michaelmas; after which it is fed down cloſe with ſheep till near Chriſtmas. It was ſown with ſpring corn after turneps, but the owner was of opinion, that if the field had been ſummer-fallowed for it, the Lucern would have entirely choaked all other graſs and common weeds.

Some Dutch Clover and Ray-graſs grows with it, which is found advantageous. One part of the field was well manured with dung, and the owner propoſed doing the ſame by the reſt of it; and after harrowing in february or march, to ſcatter ſome freſh ſeed, where the plants failed the moſt[4].

It having been found by repeated experiments that broad-caſt Lucern will not ſucceed upon lands that are not perfectly clean, Mr. St. Leger adopted the following method.

In the month of auguſt, he mowed the graſs from one acre three roods, and immediately after the hay was removed pared and burnt the ſurface. The aſhes were put into two heaps, and covered with ſods. The ground was then ploughed as deep as its ſtaple would admit of. On the 11th of november he harrowed it with heavy harrows, and on the 25th ploughed it acroſs. On the 4th of january it was harrowed again. One heap of the aſhes was ſpread on the 23d of march, and on the 2d of april the land was ploughed and ſown with lentils. Had the weather permitted they would have been ſown immediately on ſpreading the aſhes. At the beginning of auguſt the lentils were cut, and the other heap of aſhes was ſpread upon the ſurface; after which the land was ploughed, and immediately ſown with turnep-ſeed. The turneps were well hoed, and produced an exceeding good crop. Being late ſown, they conſequently kept later in the ſpring than ſuch as were ſown at the uſual ſeaſon.

In may following the field was ſown broad-caſt with Lucern-ſeed, after being properly ploughed and harrowed. The quantity of ſeed 12lb. to the acre, ſown at twice. The firſt ſeaſon the plants ſhould be hand-weeded, being then very tender; but the ſucceeding years, when the roots have penetrated the ſoil, the land ſhould be run over with very heavy harrows, after every cutting, to tear up the graſs and weeds.

After the froſts are over, and vegetation begins, the land may be harrowed, if foul; but if clean, that operation will not be required till after the firſt cutting[5].

Mr. Fitch, of Pluckley in Kent, had two acres of broad-caſt Lucern, ſown twenty years before with barley; when Mr. Belcher viewed it, the plants were in patches or ſingle, often two or three feet apart, yet it produced four tons of hay on an acre, at three cuttings. Its having ſtood twenty years without culture, is a proof that it will thrive on ſome ſoils, even when the graſs is become a turf. It ſhows alſo what a large ſpace plants of Lucern will fill; and confirms Miller's aſſertion, that he had a plant, whoſe crown was eighteen inches in diameter, from which he cut near four hundred ſhoots at one time[6].

Drilled Culture.

When the rows are come up, and weeds begin to appear, in dry weather a ſhim ſhould be run between them, to cut up the weeds and looſen the ſoil, and a hand-hoeing and picking ſhould follow to clear them perfectly. Theſe operations muſt be repeated, as they are wanted. The year following, ſo ſoon as the land is dry enough in the ſpring, and through the whole ſummer, it muſt be a conſtant conflict between the ſhim or hoe and any weeds that may appear. The crop muſt be kept conſtantly and abſolutely clean; but the principal attention is to be given immediately after every cutting, the weeds being then beſt diſcovered and moſt eaſily deſtroyed, particularly by the horſe-hoe, where the rows are wide enough to admit of that inſtrument. If the rows be very ſtraight, the ſhim is of great uſe, becauſe it may be directed ſo near the rows as to ſave much hand-hoeing; and for getting out ſuch weeds as grow among the plants a pronged hoe is of much ſervice.

A field of Lucern ſhould never be weedy under a notion that the crop will mow well and free from duſt; for if it be as luxuriant and thick as it ought to be, provided the rows are nearer in proportion as the ſoil is poorer, there will be no difficulty of that ſort[7].

Mr. Belcher, who prefers drill-ſowing of Lucern in general to broad-caſt, directs it firſt to be cleaned by hand, and when it has obtained ſtrength, to have the plough drawn deep between the rows after each cutting, eſpecially ſome time after the laſt, at the end of october, the beginning of november, or later, at which time boards may be fixed to the plough, and the ground left in ridges till towards the ſpring, the end of february, or beginning of march, or later, before it is harrowed down again[8].

This winter-earthing the Lucern is of ſingular benefit in ſmothering the natural graſs, the arch-enemy of it, in our moiſt climate: and the vegetation of Lucern being at a ſtand during the winter, it does not ſuffer from the excluſion of the air any more than artichokes or aſparagus. Mr. Belcher regards this operation as the corner-ſtone on which the profitable cultivation of this crop depends, in a moiſt climate[9]. And yet it has been tried by others without any ſucceſs, and has been found to retard the growth much, and even to deſtroy it[10].

In drill-ſowing ſo ſmall a ſeed as that of Lucern, it is a good way nearly to fill a bottle with it, and having corked the bottle, to bore a hole through the cork, and to inſert a large quill cut at each end, or a ſmall tin tube, ſuch as ſeedſmen uſe to tap ſacks of ſmall ſeed, to draw a ſample[11].

Mr. Belcher has given a journal of a field of Lucern for the three firſt years. It contained an acre and three roods, had been an old lay, but under corn for ſome years laſt paſt, good land, but ſomewhat too light in his opinion for Lucern.

Between may the 9th and the 16th he ſowed eighteen pounds of Lucern, and the ſame quantity of clover ſeed, in alternate fifteen-inch rows, out of a flat quart bottle, through a hole in the cork, by a line, covering the ſeed with a hoe. A ſhower on the 12th brought up much of the firſt ſowing in ſix days after, the

[11] Id. 13. 49.

ground being extremely dry before, and cold afterwards. Towards the end of june he hand-hoed and hand-weeded: in fome places it was eaten by the fly and weak, weaker in general than the clover, but in the beft places higher. September the 6th began to mow them for the team, the clover producing the moft by much; together a load on an acre, had it been made into hay. The horfes eat it promifcuously. Stocked it after mowing with lambs and riders till the end of october, being a very dry time. At the beginning of november earthed for experiment feven rows of the Lucern as deep as poffible, deftroying the clover, alfo earthed fhallowly the remainder of the Lucern, except eleven fhort rows, by turning the earth with one board over it from the clover on both fides, uncovering it afterwards (fome earth having fallen on it) except a few fhort rows. The crop was very fmall, the ground confidered, but the fummer was very dry.

The fecond year on february the 23d uncovered part of a row, to fee if doing it earlier than common were of importance. On the 27th it was preparing to fhoot. On the 28th it was harrowed all down, the feven deep-earthed rows more than the reft. March the 24th it began to advance, but irregularly. That which was not covered at all was the eveneft; and the feven deep-covered rows were the worft of all, fome of the plants being feemingly deftroyed. However covering had the propofed effect of fmothering the natural grafs. From this inequality in coming on, it feems that Miller's obfervation, that it may be fed, it paflure run fhort, from the middle of march to a week in april, is a very good one: for then, growing away together, it will be ready for cutting nearly as foon as if not fed. April 12th the Lucern was advanced confiderable in fpite of very cold weather; the feven deep-earthed rows ftill the weakeft. The row of clover left covered through the winter now much inferior to the reft, but being thinner, flourifhed much afterwards. On the 30th obferved the eleven fhort rows not worked at all to be yellower than their neighbours. May the 23d began to mow the Lucern and clover, though not ready, except for fwine; but was fearful the clover, which was much the ftronger, would damage the Lucern by overhanging it: the feven deep-earthed rows were now the moft vivid and ftrongeft of all. June the 6th the clover fhowed for bloom before the Lucern. Rakes with longer and more diftant teeth than common, get Lucern up cleaner from dirt. In july, perceive that wet and cold check the growth much, and that it even turns yellow; but reviving and growing profligiouffly in fucceeding hot weather. Some unmowed plants did not flower till this month, though the Lucern and clover, cut as mentioned, began to blow on the 20th about two months afterwards, the former being now between two and three feet high. At this time it was mown again a fine crop, and in feptember afforded an inferior one; the feven rows prodigiouffly the ftrongeft. After the third crop the pafturage by no means contemptible; and a part fenced afforded good mowing till november. Towards the middle of that month broad-fhared the clover up, earthing the Lucern at the fame time with mould-boards, twenty-two inches wide at the extremities. A forward or backward fpring will make a month's difference in its advance.

The third fpring, a backward feafon, on the 16th and 17th of march, boxed a bufhel of tares an acre between the rows, after the ground had been loofened with the plough-fhare: it was afterwards harrowed down. April 1ft, being a fine growing time, the Lucern begins to poth. On the 19th fharp frofts have laid down the forward fhoots; it being unequal as ufual in the fpring. May 7th to the 9th filled up vacancies, planting two plants in a hole made with a hoe-pitcher, in a fine moift time. On the 20th began to mow for fwine, the beft being fifteen or fixteen inches high. June the 1ft began for the horfes. On the 11th where the Lucern is weakeft, the tares are a foot high, being mown together for the firft time. July the 9th began to cut it again; a fine crop of both, than which there is no better provender for horfes; it is alfo excellent for fwine. Seed fown in fome vacancies in the fpring now coming up. Hoed round the plants fet in may. Some of the ftrongeft Lucern had grown twenty-four inches in as many days; fo that though a backward fpring, four good crops might have been cut, yet it ftackens in its growth towards autumn.

Hence the great value of Lucern muft be acknowledged for fummer keep for teams in particular. Every one knows the precarioufnefs of annual graffes; but in Lucern the farmer has a proviflon for his cattle, nutritious, plentiful, early and fure. Still to enhance it, part of the plantation may be fown with tares; and part with white oats; in order to cut for the firft crop the part under which are the tares before they are advanced, for the fecond that with the oats, and thirdly that with the tares the fecond time. This laft will be a prodigious crop, and by matting together, powerfully fubdue the weeds. It muft be a very indifferent acre that will not keep a horfe the fummer, and a very good one will maintain two[a].

From fuch minutes of experiments much more real information is acquired than from volumes of theory.

Tranfplanting.

The method of tranfplanting Lucern invented by Monf. du Chateauvieux, and treated in an elegant manner by the late Mr. Harte, in his Eflays, is particularly applicable if the foil be dry only to the depth of three feet, and then is very wet, for upon fuch land Lucern, left to run down with its tap root, will foon perifh; or upon any foil of very great fertility: on fuch land the crop fhould be thin.

The feed, for tranfplanting, fhould be fown in the fpring, and early, in order to have fizeable plants for this cafe in auguft following. It is beft fown in drills, and the young plants may be much aflifted in their growth with a fmall hand-hoe, fuch as gardeners ufe among onions. The management of tranfplanted Lucern whilft growing muft be the fame as the drilled crop; only the firft feafon, that being fet in auguft, will only want one or two hoeings in the autumn[b].

Mr. Harte's experiments and directions are the following. In the end of march a common day-labourer was ordered to fow a pound and a half of Lucern feed, and to keep the ground clean from weeds. This fhould not be done in a very dry feafon, and efpecially in fevere parching winds. By the middle of auguft fome of the plants were eighteen inches high. Taking the advantage of a moift feafon in the beginning of September, which was however three weeks too late, the roots were dug up carefully, the long tap-roots were cut off eight, nine or ten inches below the crown of the plant, the ftalks were clipped about five inches above the crown, and the plants were thrown into a large veffel of water which ftood in the fhade. The fame day, with a dibble or fetting-ftick, filling every hole with water before the roots were put in, they were tranfplanted in rows, two feet afunder, and each plant fix inches apart in the rows. The roots were placed firmly in the ground, and two inches of the ftalks covered with mould. The rows were too narrow, and the plants too near, even though the ground was poor: nor was it foreſeen that horſe-hoe ploughing is five times more efficacious, as well as cheaper than hand-hoeing. After frequent experiments it appeared beft to make the lines three feet four inches diftant, and when the foil is good, to allow each plant a foot diftance in the lines: thus the hand-hoers will work more commodiouſly, and a little hoe-plough may be guided fafely up and down the intervals; the plants will be larger, more juicy and better tafted; for fpace and culture improve the herbage of plants. Nor will the quantity be leſſened by fuch thin planting fo much as might be imagined. A friend of Mr. Harte's having planted an acre in rows of two feet, the foil being extremely good, and the crop free from weeds, it foon appeared that the roots were too cloſe. Next autumn therefore he took up every alternate row and plant, and a freſh acre of land being properly prepared to

[a] Young's annals, 1. 314. [b] Id. 25. 89, &c.

receive them, he thus gained a new plantation at ſmall expenſe and trouble: and the ſecond acre, as was thought, bore a larger quantity of herbage than the firſt would have done, if it had continued without being thinned.

In ten days after tranſplanting, though a drought ſucceeded, ſome of the plants made ſhoots of three inches. In the ſpring it was found that out of four thouſand roots only thirty or forty periſhed. The labourer filled up the vacant ſpaces from the nurſery in about an hour; and in april moſt of the plants were nearly equal in ſize and ſtrength, of a deep juicy verdure, with few or no diſcoloured ſickly leaves. On the 8th of may ſixty ſtems were counted on one root, and the produce of ſome choſen plants weighed near half a pound at one cutting. Yet Lucern is in a progreſſive ſtate till the third ſummer after tranſplanting, and then Monſ. Duhamel aſſures us, that one flouriſhing plant will produce a pound of well-dryed hay; which muſt have weighed four pounds when it was green. This is much more than it ever yielded in England; here however many plants, the ſecond year, have produced near half a pound of hay each.

As an acre of Lucern thus managed will contain about twenty-ſix thouſand roots in two-feet rows, at ſix inches diſtance in the row, and conſequently half that number in four-feet rows, at a foot diſtance in the lines, how great will be the produce of four or five cuttings every year, allowing only a pound of green fodder, or a quarter of a pound of hay to each plant at every cutting; and that confeſſedly the moſt nouriſhing and palatable food that cattle can eat. Thus much is certain, among other advantages, that if a field be induſtriouſly hoed, ploughed in the intervals, and hand-weeded in the rows, for the firſt two or three years, it is almoſt certain, that ſcarcely a ſingle weed will be found among it.

The proper time for cutting Lucern is when the plants are fifteen or ſixteen inches high, at an average; for ſome plants will be higher, ſome lower, according to the circumſtances of health, ſpace, ſituation, &c.

The cuttings of the ſecond year of the tranſplanted Lucern were on may the 8th, june the 7th, july the 12th, auguſt the 20th and october the 1ſt.

In the third year it was cut five times, and ſix times in the fourth; which make ſixteen cuttings in three years. The ſixth cutting, however, if it be after the firſt week in october, is little more than nominal. In the laſt year, by the 9th of april, ſome of the plants were near ſeventeen inches high, at a time when no field in the neighbourhood had graſs of four inches height, five or ſix acres being taken together. The crop was cut twice, before any hay-making began in the country round, excepting in ſome few meadows lying near market towns.

Tranſplanted Lucern has two advantages over that which is drilled, and ſtill more over broad-caſt: firſt, that each root will ſtand at a proper diſtance from its neighbour, and receive its due proportion of nouriſhment: or if a few ſets chance to fail, they may be ſupplied from the nurſery, any moiſt day, from april to the middle of ſeptember: ſecondly, by cutting the tap-root, it is prevented from penetrating ten or twelve feet perpendicular into the ground, which it naturally does in three or four years, except it be obſtructed by a ſtratum of rock, or chilled at root by weeping ſprings, or find admiſſion into a bed of cold clay; in all which caſes the crop makes a poor appearance, or goes off all at once.

When Lucern becomes languid and diſcoloured, probably ſome inſect has attacked the root: in that caſe a dreſſing of ſoot is expedient.

Lucern ſhould never be grazed, the crown of the root being ſo ſweet, that cattle and eſpecially ſheep will often bite it too cloſe, and heavy beaſts will bruiſe it with their feet.

For the nurſery, ſixteen perches, with good management, may be ſufficient to furniſh ſets for an acre; but it will be more prudent to allow thirty perches, and four ounces of ſeed at leaſt to each perch; thus making allowances for accidents, and having a reſerve for deficiences in the plantation. The ſeed ſhould be ſown in the ſame manner as turneps, in moiſt weather. The ground for the plantation ſhould be well ploughed and harrowed, or if ſmall dug, and picked clean from weeds, roots, ſtones, &c.

Lucern for the nurſery is beſt ſown in april, but it may be ſown in may or any part of june, in warm moiſt weather. The late-ſown will not be fit to tranſplant in auguſt, but in april following. Thus there will be a choice of two ſeaſons for tranſplantation inſtead of one.

The plants ſhould be taken up from the nurſery, in a moiſt time, with a ſharp ſpade, and no more than can be tranſplanted before night.

The expenſe of preparing the ground, tranſplanting, and hoeing an acre, including nurſery and ſeed, will be 6l. 12s.

It will always be found moſt convenient to horſe-hoe the intervals the third day after each cutting; for by that time the new ſhoots will make the plants viſible, nor will any ſide branches ſtand in the plough's way. A man and one horſe, with a boy to lead him, will eaſily do an acre in a day. It will be proper alſo to hand-weed the lines once a year; and the larger weeds may be taken up expeditiouſly with the three-pronged ſpade. It is more adviſeable to cut Lucern with a rasp-hook than with a ſcythe. A boy may cut enough this way in an hour to feed four large horſes a whole day[1].

It is obvious to remark from this ſhort abſtract of a very diffuſive account, and eulogium of tranſplanted Lucern, drawn up with much elegance, learning and claſſical alluſion by the late Rev. Mr. Harte, that among many excellent obſervations, there is much theory, and ſome miſtakes. Theſe are remarked incidentally in the following very ſenſible eſſay on the culture of Lucern by tranſplantation, by a writer under the ſignature of Mago, in the fourth volume of Muſeum Ruſticum.

On the 17th of july a field of three acres and a half then under ray-graſs and clover was ploughed deep, and ſown with turneps. By the 27th of march following, the field had been twice ploughed, the firſt time ten, and the laſt time near twelve inches deep, with the Rotheram plough and four horſes abreaſt: the ſoil light and ſtony, with a rock of gravel ten or twelve inches deep, and had never before been ploughed above ſix or ſeven inches deep.

The field was ſown with Poland oats, and about twenty-eight rods were laid out in beds four feet wide, which were ſown with Lucern ſeed broad-caſt, as cabbages are ſown in ſeed-beds; except one bed, which was ſown in drills, at ſix inches diſtance, and half an inch deep. This bed afforded much the greateſt quantity and the fineſt plants, and was kept clean with more eaſe and at leſs expenſe. The drills were covered with care, by the back of a rake. By the middle of auguſt the plants were moſtly in bloom, when they were mown and given to horſes and cows.

The oats being got in, the field was deep ploughed again. A ſeaſon of rain was waited for, which did not arrive till the 15th and 16th of ſeptember; when the field being firſt well harrowed, tranſplanting was began on the 17th and continued to the 23d. There was no difference between the firſt and laſt planted; it is however better to plant earlier if poſſible, and from the laſt week in auguſt to the middle of ſeptember ſeems a proper time. But filling each hole with water, making drills and half filling them with tea ſand or wood aſhes, and watering each plant, as Mr. Harte adviſes, is an endleſs and very expenſive work, that can be done only in a garden or very ſmall piece of ground.

The field was ploughed as level as poſſible, and then the ploughman went three times on each ſide the furrows, ſo that when harrowed acroſs they could hardly be diſcovered.

Two men with ſpades dug up the plants; and two women cut them, ſix or ſeven inches long in the root, and the tops to about two inches, taking them up one by one, in order to throw by the ſmall ones, and when they had about a dozen, cutting them at top and bottom

[1] Eſſay 2. 24, &c.

with one ſtroke of a ſharp knife at each end. Each woman had a tub by her ſide, filled within about ſix inches with water: as they cut the plants, they ſet them in the tub; and as they filled one tub, another was brought. This operation may be performed in the afternoon preceding the day of planting; the plants receiving benefit by ſtanding all night in water.

Men who are uſed to work in gardens will do the work of planting, in the ſame method as for Cabbages, with a dibble or planting ſtick. The rows were twenty inches apart, and the plants ſix inches in the lines; thus they may be kept clean with the ſingle cultivator of Monſ. du Chateauvieux; or if not, by drawing the alternate rows, they will ſtand at the diſtance preſcribed by him and Mr. Harte.

The latter of theſe gentlemen cut each plant with ſciſſars, which muſt be very tedious work; women however would handle a large pair, and cut a handful of plants with this inſtrument more readily than with a knife, and equally well. Mr. Harte alſo directs the plants to be cut to the length of nine or ten inches. Six or ſeven inches ſeems a much better length; for the ground being dug or ploughed twelve inches, the new roots will have five or ſix inches of well-looſened mould to ſtrike into, and if gravel or a ſtrong clay be near the ſurface, this muſt be a great advantage to the plants. Yet Mr. Harte ſays, that he cut his tap-roots too ſhort. The length in my opinion ſhould be fixed to the depth of the ſtaple. He alſo ſays, that he knew not how to manage a root that was very ſmall. The beſt way with ſuch is either to replant them in the nurſery if they are likely to be wanted, or if not, to throw them away.

Mr. Harte's calculation of the expenſe muſt throw a ſtumbling-block in the way of cultivating Lucern by tranſplanting, with moſt gentlemen and every farmer.

Mago calculates the expenſe on an acre as follows:

Digging ſixteen rods for the nurſery, at 3d	0	4	0
Seed three pounds, at 1s.	0	3	0
Weeding the nurſery twice with the three-inch hand-hoe	0	3	0
Ploughing	0	10	0
Tranſplanting	1	5	0
Hand-hoeing the plantation once in October, in dry weather	0	5	0
	£. 2	10	0

This is the full expenſe of making the plantation; yet the author of the Eſſays has worked it up to 6l. 12s. an acre.

If the ſpring-ploughing for barley or oats has been nine or ten inches deep, then a ploughing in autumn of twelve inches will be ſufficient, and cannot be charged at more than 10s. The trenching for the ſeed-beds may be done at leiſure time; ſo may the weeding of the nurſery, and the hand-hoeing of the plantation: then the real expenſe to the farmer will be only the ſeed and tranſplanting, or 1l. 8s. the acre. As to yearly charges, the plantation having been weeded in october, will lie very well till the end of february or the beginning of march: then, in dry weather, it may be hand-hoed again, at 5s. an acre; to which add four horſe-hoeings after each cutting at 11s. which makes 16s. an acre the annual charge. If Mr. Harte has let the charges too high, I much fear that Mago will be found to have let them too low.

Mr. Harte, enamoured with his favourite mode of tranſplantation, has certainly let the advantage of the broad-caſt culture much too low, when he ſays that it may laſt two years, only one crop being tolerable, and then muſt periſh. He muſt, as a traveller, have ſeen it do much better on the continent, where they practiſe no other method, and yet cut good crops for ſeveral years; but it is to be ſaid that in our moiſt climate the natural graſs and weeds will quickly overbear it, this is in ſome degree true: but yet if the land was clean, with good harrowing, it may laſt ſome years, perhaps ſeven or eight, and may be cut three or four times in a ſeaſon. To cut it four times indeed, the ſummer muſt be very favourable, and the laſt cutting will be late; nor will it be fit for cutting ſo ſoon as drilled or tranſplanted Lucern by a fortnight or more.

Early graſs.

The early ſpringing of Lucern is one of its moſt valuable properties. It may be depended on for much earlier food for ſheep and lambs than any graſs, and in rich warm land will yield a feeding of ſome account by the 20th of march, and continue very productive all april, which is the ſeaſon that the ſheep-maſter is more diſtreſſed than at any other time of the year. Sheep muſt not however be kept on it in ſuch numbers, and ſo long as to make them eat into the crown of the plants, which damages them much; they will not however do this whilſt there are any young ſhoots[1]. Mr. Harte mentions its being ſeventeen inches high on the 9th of april, when graſs was only four inches in height, and that it was cut twice before hay-making begun. Its earlineſs however in the ſpring is uncertain, and of courſe muſt depend upon the ſeaſon.

Number of Cuttings.

The proper time of cutting graſſes, and this with other leguminous plants, vulgarly called artificial graſſes, is when they are in full bloſſom; but this rule can only be followed for hay. The beſt uſe of Lucern is for ſoiling, and conſequently ſuch portions of it ſhould be ſet out for every day as will inſure a conſtant ſupply. Broad-caſt crops will not grow ſo faſt as thoſe which are drilled or tranſplanted, nor uſually yield more than three full growths in the ſix growing months, though the number aſſigned by Mr. Rocque is from three to five; a broad-caſt field therefore ſhould be parcelled out into ſixty diviſions, one to be cut every day. Drilled and tranſplanted crops, on good land, may be diſtributed into forty diviſions; but on very fine land, into thirty. By this means, which of courſe is to be varied as the cultivator finds the growth of his crop, he will always have a ſucceſſion ready for the ſcythe. The growth, on well cultivated rich land is very great, riſing to eighteen inches in thirty or forty days, and yielding five good cuttings between april and ſeptember[2].

The number of cuttings aſſigned by Columella is from four to ſix. In Catalonia it is cut from four to ſix or even ſeven times in a ſeaſon, though broad-caſt, all exceedingly thick and fine from two and a half to three feet in height when cut. But it is all watered every eight days. It would yield ten tons green on an acre at each cutting, and much of it a great deal more: if we ſuppoſe five cuttings or fifty tons an acre, this at 16s. a ton, is 40l. ſterling an acre. All crops in England ſink very much on compariſon with the vaſt and luxuriant burthens given by theſe watered grounds. The fineſt crops with us are drilled, but the eye is deceived in drilled crops in proportion to the diſtance of the rows, they appear thick when they are not really ſo; but in broad-caſt ones there is no deception; and thoſe immenſe burthens, through which the ſcythe is with difficulty moved, produce more at one cutting than two-feet drills would at three with the advantage of the herbage being finer and ſofter. But weeds in England and Catalonia are very different things: it well deſerves however, with us, a better trial than it has yet generally received. Rocque's broad-caſt crops on a rich garden ſoil, and Dr. Tanner's on a common turnep loam, were certainly encouraging[3]. Mr. Rocque ſays that his crop yielded near eight loads of hay on an acre.

I have ſeen many years together a crop drilled at twenty inches, in very indifferent land, cut ſix times every ſeaſon. And Dr. Anderſon informs us that he has cut a plant of Lucern ſix times in one ſeaſon, allowing it to be about twenty inches high before each cutting. He adds a very good remark, that this and other ſucculent plants, ſuch as Clover, may be conſumed moſt profitably as green fodder, becauſe as ſoon as they are cut, they quickly vegetate afreſh during ſummer; puſhing out very vigorous ſhoots which advance with great rapidity until the plant has attained nearly its full ſtature; after which it advances more ſlowly, till at length it becomes ſtationary, and is employed ſolely in maturing its fructification. It ſhould

[1] Young's Ann. 25. 96. [2] Id. ib. [3] Id. 8. 242.

be cut therefore when it approaches the ſtationary ſtate, and thus a much greater quantity of vegetable food will be produced, than if it were allowed to arrive at greater maturity before each cutting [r].

Lucern in ſmall quantities is ſown in gardens or plats where it is not convenient to turn in cattle to feed, in this caſe it muſt be cut as often as it is fit, which will be four, five or ſix times. But where cattle or ſheep can be turned on, it is generally better to feed it in ſpring and autumn, and to take only three cuttings, which will be good ones, provided it be not ſtocked ſo hard as to damage the bulb or crown of the root. If it be not fed, a middling unequal crop may be cut at the end of april or beginning of may, a ſecond about the firſt week in june, a third the ſecond week in july, a fourth the third week in auguſt, theſe three will be full crops, and a fifth at the end of ſeptember or beginning of october. This will generally be of little worth: and allowance muſt be made in the others for ſoil and ſeaſons. Mr. Harte mentions its being ſeventeen inches high on the 9th of april; I have ſeen it eighteen inches high on the firſt of may; and have known it hardly fit to cut the firſt time till the 27th of may, or even the 3d of june, in untowardly ſeaſons.

The reaping-hook or ſickle has been recommended for cutting it, in preference to the ſcythe: this may do where ſmall parcels are cultivated, and where the rows are forty inches aſunder; but in broad-caſt and cloſer-drilled Lucern, the ſcythe will do the work very well, and for leſs than a fourth of the expenſe. The Lucern ſhould be gathered into a one-horſe ſkeleton cart, and carried directly to the ſtable door, if it be for ſoiling horſes [s].

Duration.

Broad-caſt Lucern, with good management, may laſt ſeven or eight years. Columella and Palladius aſſign a life of ten years to it, and Pliny of thirty. Harte follows Columella. Monſ. du Chateauvieux gives it twenty years. Dr. Anderſon ſays that it laſts from twelve to twenty years in a favourable ſoil, but declines at laſt and dies away. Some aſſign eighteen or twenty years to it, and others only nine, or at moſt ten or twelve. Tull gives it a life of ſixty years. I do not know that it has ever been ſuffered to ſtand ſo long, but I have little doubt of its attaining that age, in a good ſoil, with proper management. In that caſe, aſſiſted with manure, I have not obſerved it to decline at any age. It does not attain its full vigour before the third, or according to others, not until the fifth year. This therefore is an objection to ſowing broad-caſt, which declines and even wears out very faſt after the ſeventh or eighth year.

Manuring.

Upon ſoils not of extraordinary fertility manure ſhould be occaſionally beſtowed upon this crop. Rotten dung is the beſt ſpread upon it early in winter; about twenty tons to an acre once in five or ſix years will be an ample allowance. If dung cannot be ſpared, ſoot or aſhes may be ſubſtituted [t].

Rocque recommends freſh ſtable dung to be laid on before the laſt ploughing, and ploughed in directly, as a preparation for ſowing.

Mr. Belcher directs pond mud, which has lain in a heap all ſummer, to be carried on in winter, after it has been well ſhaken by the froſt, fifteen hundred buſhels to the acre [u].

Mr. Harte recommends wood-aſhes, ſoot and lime as proper dreſſings for ſtiff, cold, clayey lands; for hot, ſhallow, brathy ground a compoſt of calcined clay, rotten dung, and pond-mud, long expoſed to ſun and froſts, and frequently turned; and for ground of a middle nature, malt-duſt. But as variations of ſoil are infinite, the compoſt-dunghill is the ſureſt aſſiſtant.

Dung is probably not one of the beſt manures for Lucern, except it be very old, and corrected with mixtures of a ſweet and fertilizing nature. For dung, if new, produces very luxuriant troubleſome weeds, and gives the crop a foul taſte. No dung, even of the beſt kind, muſt be ſpread on Lucern, till it be two years old at leaſt.

In moiſt grounds, eſpecially of a clayey caſt, preference ſhould be given to ſoot-dreſſings, then wood-aſhes ſecured from wet; next ſoap-boilers aſhes, coal-aſhes well fitted, charcoal-aſhes, and malt-duſt, ſown over the crop in the ſpring. Nor might the aſhes of lime be amiſs, nor lime itſelf mixed with mould under turf. The compoſt-dunghill thrice turned will ſpread almoſt as well as aſhes or ſoot, and will be very rich if it was moiſtened with brine, ſoap-ſuds, urine, &c.

With ſoot, aſhes, lime, &c. it is ſufficient to dreſs the rows only, becauſe they may be diſperſed very exactly, in the Berkſhire manner, with a peat-aſh ſpoon: but old dung, marl, compoſt-dreſſings, and other coarſer manures, ſhould be laid on the intervals as well as rows. Seven or eight buſhels of ſoot, mixed with ſand, or fifteen or ſixteen buſhels of wood-aſhes, or malt-duſt, will be ſufficient for an acre, ſown on the rows in moiſt weather, and renewed occaſionally. A labourer, with a peat-aſh ſpoon and ſeed-lip, may ſprinkle the rows of an acre, with ſoot or aſhes, in four or five hours [x].

Produce.

The produce of a Lucern crop, like that of all others, will depend on ſoil and management. They reckon in ſome parts of France that an acre of it produces more than ſix acres of good graſs, in others, as much as three only; and of hay, more than four tons. Some of their crops have riſen to nine tons. Mr. Wynn Baker mentions eight tons of hay to the Iriſh acre, which is five to the Engliſh meaſure. Others ſtate good crops at from twenty to forty tons, and twenty-five at an average. Duhamel mentions forty tons; and near Barcelona the produce of green fodder amounts to fifty tons on an acre in one ſeaſon. Rocque at Walham Green got eight loads an acre at five cuttings; and to the value of 35l. for ſoiling [y]. Mr. Harte, the firſt year after tranſplanting, had about eight tons from an acre. Mr. Baldwin had above fourteen tons from four cuttings. From an acre of broad-caſt, cut july the 15th, near five tons and a half, and two more crops were produced, from four acres and a half, ſeven years old, eighteen loads of hay were produced; and forty eight loads from another field of eleven acres [z].

The Rev. H. J. Cloſe, of Trimley in Suffolk, from ſomewhat more than half an acre of tranſplanted Lucern, the ſecond year, had eight tons two hundred and forty-one pounds of green food at five cuttings [a].

In the ſecond year after tranſplanting, when Lucern is not yet arrived at its full ſize, and at the firſt annual cutting, which is not the beſt, Mr. Harte weighed a parcel of the prime plants, which one with another were about a pound and quarter each. But ſuppoſing that every plant weighed only one quarter of a pound, and admitting we give up the ſixth cutting; then the produce is at leaſt ten tons of green Lucern on an acre. He calculates that an acre of tranſplanted Lucern, rightly managed, will bring in 5l. a year, free and clear from all expenſes, and that for a conſiderable tract of time [b].

Some perſons are of opinion that conſtant mowing exhauſts the crop; that however does not ſeem to be the caſe, but on the contrary agrees better with it than leaving it for a full crop of hay: yet even thus the advantage is conſiderable; for at three mowings a good acre will produce four tons of dry hay, and ſometimes even five; which, though it does not greatly exceed two cuttings of clover, yet conſidering that the latter is exhauſted in one year; and that Lucern laſts as long as you pleaſe, is a very great ſuperiority [c].

Application.

One of the beſt uſes to which Lucern can be applied green, is for ſoiling of horſes in the ſtable, no food agreeing better with them. Mr. Baldwin found that an acre would keep five horſes twenty-one days, at 90lb. a day to each horſe. Mr. Hall's broad-caſt

[r] Eſſays, 2. 26. [s] Young's Ann. 25. 97. [t] Id. 15. [u] Id. 4. 14.

[x] Eſſays, 2. 108. [y] Young's Ann. 25. 100. [z] Weſton's Tracts, 288. [a] Bath papers, 3. 61. [b] Eſſay, 2. 118. [c] Young's Ann. 25. 99.

crop paid him for seven years together 11l. 6s. an acre, by feeding horses at 2s. 6d. a week. Sir John Turner's, also broad-cast, kept five horses twenty-six weeks, which at 2s. is 13l. an acre. Mr. Butcher's at Chalk in Kent, a seven years old, maintained six horses to an acre, from may day to michaelmas. Mr. Reynold's broad-cast, kept four horses to an acre, from the middle of may to the middle of october; which at 2s. 6d. is 11l. 10s. an acre. Mr. Vernon's in Suſſex, drilled at two feet, kept five horses on an acre from the beginning of may till the middle of october, which at 2s. 6d. is 12l. 7s. 6d. Dr. Lloyd's of Puddletown, in drills at eighteen inches, maintained four horses to an acre eighteen weeks, which at 2s. 6d. is 9l. Mr. Anderſon's, drilled, in the fourth year, produced 9l. to an acre, and 5l. 9s. profit. The fifth year, 6l. 15s. profit. Mr. Clayton's broad-cast crop fed five horses on an acre, to the value of 9l.; and his drilled crop, four horses or 7l. 4s. Roque reckons that three quarters of an acre maintained three horses[a]. Mr. Belcher affirms, that it muſt be a very indifferent acre that will not keep a horſe the ſummer, and a very good one that will maintain two. He informs us however that Mr. Fitch kept four horſes from june to october, in working order, which cannot be ſet at leſs than 10l.[b]. Dr. Tanner's four acres, broad-caſt, was the chief ſupport of fifteen horſes and cows, from the end of april till michaelmas; after which it is fed down cloſe with ſheep till near Chriſtmas. Another year, five ſaddle horſes and four cows had nothing elſe to eat, and five coach-horſes were foiled with it daily[c]. Three acres of Mr. Johnſton's maintained eight horſes, from the 2d of may to the end of ſeptember, twenty-two weeks; which at 3s. comes to 26l. 8s.[d]. Mr. Dann values Lucern at 2l. 10s. an acre, clear of rent and every expenſe, mowed daily, and given to horſes and oxen, in the yard or ſtable[e]. Mr. Harte is of opinion, that a perſon muſt be an excellent manager, who can keep two good cart or coach horſes all the year round upon an acre of Lucern. For they will conſume near 80lb. of green food in a day and night, with ſome dry food beſides; and three tons and half of hay muſt be allotted for their winter ſupport during ſeven months. Now it will be difficult to maintain theſe two horſes with green Lucern, and to ſteal one cutting for hay. Nor will that hay be ſufficient, except it be mixed with ſtraw.

Horſes, ſays Mr. Harte from Monſ. Duhamel, fed with Lucern, except when employed in journies, or other hard work, will need neither oats nor beans. No food makes their coats ſo ſmooth and well coloured. But when a horſe firſt begins this ſucculent food, he ſhould have a ſmall quantity, as ten pounds, which ſhould be gradually increaſed for three weeks to twenty, thirty and perhaps forty pounds. It ſhould alſo be given in ſmall quantities, and ſlightly moiſtened with water, to ſuch horſes as are touched in their wind. It is too full of nouriſhment for hunters, and ſhould be given in leſs quantities to ſaddle horſes, than to coach and cart-horſes. When they are firſt fed with it in the ſpring, it may not be amiſs to take a little blood from them. And if thoſe who feed them can be perſuaded to give them a little and often, they will eat with more appetite, and make no waſte[f].

Lucern is excellent for foiling cows and young cattle in a farm yard, and for working oxen. A middle-ſized cow will eat from 90 to 110lb. of green Lucern in twenty-four hours. The ſame caution muſt be taken as with clover to prevent hoving or being blown. Mr. Baker found that an Iriſh acre would keep ſix cows one hundred and forty-five days; an Engliſh acre therefore would keep about four the ſame time. Sir Charles Turner kept four cows on a drilled acre[g]. Mr. Ray two cows through the whole ſummer. According to Mr. Belcher, Lucern affords very good butter before it flowers, but indifferent afterwards; the milk and cream however is never bad. To prevent its blowing bullocks he recommends it to be given them in racks with narrow ſtalls[h].

Varro and Cato tell us, that 20lb. of Lucern hay was allowed, at night only, to a working ox. Theſe and all ſorts of kine are very fond of it green; and in meadows ſown with clover or trefoil, they will run immediately to their feeder, whenever he comes near them with a burthen of Lucern. They always prefer it, when it has been cut a day or two, and remained in a dry ſhady place[i].

It has been doubted whether Lucern could be ſucceſsfully applied to fattening beaſts. Mr. Herbert however, of Mucruſs in Ireland, found that it fattened them admirably, and conſidered this as its higheſt value. Bomare ſays expreſsly that it will fatten them quickly[k]. Mr. Belcher fattened bullocks with Lucern on a hill farm[l]. Mr. Young remarks from an experiment of his own, that the effect of it in fattening is a proof of the great value of this plant; that its ſuperiority to tares is prodigious; and that when once eſtabliſhed it is far cheaper. The ſame ſecond growth which fed his beaſts three weeks, ſupported other cattle alſo, to the amount of feeding theſe ten a week and half more, which makes the value of this growth in beef ſomething better than 10l. A conſiderable return, as he obſerves, could we procure a full plant without ſacrificing a crop of corn[m].

Mr. Harte affirms, that cattle fed with Lucern may be made fit for ſale more expeditiouſly and earlier in the year, than they can be brought to market in any other common method; ſince it is very eaſy to begin fatting at the end of april, and to finiſh about the middle of harveſt, when meat bears an high price. Some caution ſhould be uſed at firſt: each beaſt ſhould loſe a little blood; and after a little time a large ox may have 40lb. of green Lucern each day, and perhaps more[n].

With reſpect to Sheep, there is ſome doubt whether they are not apt to damage the crown of the root, and thereby to prevent or at leaſt weaken the ſhoots that ſhould furniſh the ſucceeding cuttings. This ſhould be a caution not to let ſheep lie on Lucern too long. The firſt growth in the ſpring is of great uſe for ewes and lambs. Mr. Baldwin fattened Welſh wethers on it with great ſucceſs. It is beſt given them in racks. It may be fed after the laſt cutting, in dry weather with any kind of ſtock, in wet weather with ſheep. Certainly no plant is more acceptable to ſheep, or more nouriſhing for them than Lucern. Mr. Harte ſays that he knows from his own experience, that Sheep will eat it green or dry, when they refuſe every ſort of food beſides; and that there cannot be a better preſervative, when the rot begins to threaten, than to give them green Lucern mixed with a little buck-bean, or Lucern-hay moiſtened with freſh brine[o].

Of Swine there is no doubt but that Lucern is excellent food for them, and they do it no damage. Mr. Belcher remarks that they like it beſt young, and that if they or any other ſtock fed with it, be pounded and well littered, the crop may thus be made richly to manure itſelf[p]. Not biting cloſe like ſheep, Swine may eat it very ſafely, and a ſmall field near the farm-yard would be uſeful for this purpoſe. It is better however to foil them with it in the yard or ſty, on account of the great value of their dung[q].

Hay.

Lucern makes excellent hay. It ſhould not be ſtirred about much, that the leaf may be preſerved. Roque directs that it ſhould be mown for hay as ſoon as the bloom appears, or ſooner, that it ſhould lie in the swarth, and be turned as clover.

Mr. Harte informs us that on the continent it ſells at a much higher price than the beſt upland hay. He would have it cut with the ſtraw-cutter, and given to horſes mixed with other hay; or reſerved for ſick horſes and cattle. Monſ. du Chateauvieux aſſerts that 2lb. of chopped Lucern-hay are equivalent to a quartern of oats.

[m] Eſſay 2. 134. [n] Id. 137. [o] Young's ann. 1. 309.
[p] Id. 25. 100.

Hay in our moiſt climate can only be made in a dry ſeaſon, for if it lie long, it not only gets damaged itſelf, but materially injures the ſucceeding cutting. If it can be carried to an adjoining paſture, that is fed down cloſe, that ſeems to be the beſt method; though an expenſive and troubleſome one, if the quantity be conſiderable. It ſeems preferable however to another method which Mr. Harte recommends; namely, to leave intervals of ſix feet, between every pair of rows, whereon to make the hay: for in the judgment of moſt perſons his rows are too wide already. Senſible of the difficulties, he does not adviſe any one to attempt making any great quantities, eſpecially ſince it is ſo valuable in a green ſtate, and four tons of it ſhrink to one in drying. He directs much care and attention in making, as ſcarcely any perſon can be expected to give, and no perſon will get done by others: and in laying it up, he adviſes layers of wheat-ſtraw to be placed between layers of Lucern[1].

After all, Mago does not think Lucern more difficult to be made into hay than clover; and affirms, that with one quartern of oats any gentleman will be well ſatisfied with the condition of his horſes, even *coach-horſes*[2].

Saving Seed.

Mr. Miller, from his own experience, commends Engliſh ſeed in preference to foreign. Others ſay that the ſeed is not worth ſaving in England. Rocque directs it to be ſaved, not from the firſt, but from the ſecond growth. The difference between Lucern from Engliſh ſeed which Mr. Belcher raiſed himſelf, and that from French ſeed was amazing; the latter being prodigiouſly ſuperior, ſown the ſame day and on the ſame ſoil[3]. The home ſeed was larger, did not come up ſo ſoon by two days, and then not near ſo thick. Near a month after the foreign was much thicker and ſtronger. In June ſix plants of each were tranſplanted, and on auguſt the 27th the produce being weighed was nearly equal in both; whence it appears that the difference was entirely at ſtarting, and they were equal afterwards.

At preſent, ſays Mr. Belcher, there is far from any reaſon to think it worth while to ſave home-ſeed, more eſpecially as Mr. Harte ſays it is injurious to the plants, which however he did not perceive[4].

Mr. Harte ſays that he has raiſed Lucern ſeed with no great difficulty in England, but that he never could ſee a reaſon for preferring it to foreign ſeed; which will be better ripened than our own, and ſome advantage will reſult from change of ſeed. However he directs thoſe who chooſe to ſave their own ſeed, to take it from the third cutting, to cut off the tops of the ſeeding ſtalks with large horſe-ſciſſors or a ſmall ſickle, juſt after ſun-riſing; to dry the pods on a winnowing-ſheet, and to thraſh them out with a ſhort ſtick, in the ſame manner with clover, and to paſs them through a very fine ſieve. After the ſeed-branches are cut off, the remainder muſt be mown as uſual, and may ſerve as fodder for cart-horſes, and lean cattle[5].

Expenſes.

One main obſtruction to the more general culture of Lucern, has I apprehend been an idea of the great expenſe attending it. Mr. Harte's eſtimate is very high indeed, 6l. 12s. But his culture throughout is adapted entirely to a gentleman. Mago in the Muſeum Ruſticum has reduced the expenſe of the firſt year to 2l. 10s. and the annual charge to 16s.

The following is another caleulation of the expenſe attending the culture of an acre of Lucern, during the firſt year.

Rent, &c.	-	1	10 0
Two ſpring ploughings	-	0	18 0
Harrowings	-	0	2 6
Eight pounds of Seed	-	0	8 0
Drilling	-	0	2 6
Horſe-hoeing in autumn	-	0	2 6
Hand-hoeing in ditto	-	0	5 0
	l.	3	8 6

Second and ſucceeding years.

Rent, &c.	-	1	10 0
Four horſe-hoeings	-	0	10 2
Three hand-hoeings	-	0	12 0
Five mowings	-	0	12 6
Raking, loading and carting	-	0	12 6
Manuring	-	0	12 0
	l.	4	9 2

Or perhaps the expenſes may not be ſet too high at 5l. where the acre is well managed and highly cultivated. Great however as this expenſe is, the crop will anſwer exceedingly well[6].

Another eſtimate of the annual expenſe of an acre of Lucern is thus given by Arthur Young Eſq. in his Six weeks Tour through the Southern Counties.

Rent	-	1	10 0
One cleaning to each of four cuttings at 2s.	-	0	8 0
Four cuttings at 2s. 6d.	-	0	10 0
Hand-weeding and cleaning the rows	-	0	10 0
	l.	2	18 0

But here is nothing charged for four horſe-hoeings; nor for carrying and manuring. If theſe charges be added to the above ſum, this eſtimate will not differ materially from the other. We may preſume therefore that a fair crop of Lucern, will at leaſt pay cent per cent, when it is once eſtabliſhed.

Mr. Young however has obſerved very properly[7], that a plant like Lucern, ſown on well-cleaned land, and kept clean by hoeing afterward, is procured at an expenſe which is ſeldom calculated fairly. Beſides the expences ſtated above, a crop of corn on good land cannot be eſtimated at leſs than 5l. And to balance this, the produce the firſt year is very inconſiderable. The ſecond year muſt be very good, to pay its own charges, and the drawback of the preceding year: now a cultivation, which at the end of two years ſhall have paid nothing in profit, is not worth attention. If it can be got with corn, the caſe is different; and foreign Lucern is all ſown with corn.

When Lucern however is ſown broad-caſt, a ſmall crop of barley or oats may be obtained, ſufficient at leaſt to pay all expenſes, without much damaging the Lucern, if the ſeaſon be favourable. Between the rows of drilled or tranſplanted Lucern, any of the crops uſually drilled may be put in, as Beans, Cabbages, &c. Or Vetches may be ſown in the intervals. Or broad Clover may be mixed with broad-caſt Lucern, or ſown in the ſpaces of that which is drilled or tranſplanted. This practice may in ſome degree meet the above objection to the culture of this valuable plant, and render it worth the attention even of the farmer in point of profit as well as convenience. But even ſuppoſing Lucern not to be ſo profitable as its moſt ſanguine friends believe, and would perſuade us to do ſo; yet ſtill it may be convenient to have a ſmall quantity for ewes and lambs early in the ſpring, for feuling horſes occaſionally, and ſupplying the deficiencies of other foddering crops.

7. *Yellow Medick*, and *Variegated Medick.*

Yellow Medick is hardier than Lucern, roots ſtronger, grows in drier ſoils, yields abundance of fodder very nearly allied to Lucern in quality, and loſes leſs in drying. In the ſandy fields of Suffolk, on the fallows, the ſtrength of its roots defies the plough and the hungry ſheep[8]. If the ſtems are proſtrate, which Linnæus makes one of the ſpecific diſtinctions of Yellow Medick, it would be an objection to the culture of it, becauſe it could not eaſily be mowed. Single plants may have proſtrate ſtems, but when it comes to be cultivated in a thick crop, the ſtems will ſupport one another; and the caſe is the ſame with Trefoil (Medicago lupulina) and many other plants.

Thomas Le Blanc, Eſq. of Cavenham in Suffolk having been ſtruck with the luxuriance of the Yellow

[1] Eſſay 2. 153. [2] Mus. ruſt. 4. 313.
[3] Young's ann. 2. 64. [4] Id. 3. 440. [5] Eſſay 2. 192.

[8] Young's Agr. 6. 50. and 15. 278.

Medick in the pooreſt ſoils, determined to have the ſeed gathered, in order to cultivate it. Whilſt engaged in this purſuit, he happened to find the Variegated Medick, and obſerving it to be more luxuriant even than the yellow, it commanded his attention.

It is leſs erect, he ſays, and leſs ſucculent than Lucern; but more ſucculent, and much more luxuriant than the yellow Medick. The ſeed pods partake of the ſhape of each, being leſs twiſted than thoſe of Lucern, but more ſo than thoſe of Yellow Medick. The flowers are beautifully varied in every ſhade of blue and greeniſh yellow, and ſome are almoſt white. His reaſons for preferring it to Lucern are, that it is hardier in bearing cold, that from its habit of branching below the ſurface of the ground, and the ſhoots being much more numerous, it is not choaked by natural graſſes, and that for the ſame reaſon it will not be injured by being fed with ſheep, and that it grows ſpontaneouſly upon the pooreſt ſoils.

In 1783 he began with a ſingle plant, which he tranſplanted into his garden, the ſoil of which is a blowing ſand. In 1784 he gathered the ſeed of it, and in april 1785 he ſowed with it a bed conſiſting of five rows, thirty-nine feet long. The plants came up thick and ſtrong; ſome of them bloſſomed at the beginning of july in the ſame year, and meaſured above two feet in height. Although all the ſeeds were gathered from one plant, yet the flowers differed very much in colour; ſome being almoſt yellow, ſome almoſt white, and others purple of various ſhades. In auguſt the ſame year he took up the ſeedlings, ſix thouſand ſix hundred in number, and tranſplanted them. Some of them meaſured two feet and a half in height. Moſt of the roots were cut through with the ſpade; one which was pulled up meaſured two feet nine inches in length. He likewiſe dug up a few wild plants, which he divided into a great number of ſlips, every one of which grew.

In june 1786 he cut down the garden plant not yet in full bloſſom; it was above five feet high, and weighed four pounds and a half. September the 6th he cut it again when it was only beginning to flower, and it weighed twenty-ſix ounces. The 29th of auguſt he cut ſome plants for ſeed; much of it was loſt by lying on the ground, the ſeaſon being wet; much alſo was unripe, and many young ſhoots were in full bloſſom. The 4th of december the plants were not affected by the froſt: at the ſame time the ſhoots of Lucern were entirely deſtroyed.

In february 1787 he obſerved many healthy young plants, ſelf ſown, where he had ſaved ſeed the preceding year, ſome of them an inch and half high, which muſt have come up before winter, and have ſtood the froſt unhurt; the ſituation indeed was ſheltered. At the end of february Le Blanc's Medick was not ſo forward as Lucern. A few days afterwards, both were equally cut off by the eaſterly winds. In december, he allotted for farther experiments, a piece of very poor ſandy land, containing five roods; it had borne Saintfoin, which was quite worn out; and he had juſt taken from it a crop of carrots: the ground was by no means ſo clean from couch-graſs as it ought to have been: the ſubſoil ſand, and to a great depth. A bottom of chalk would probably be more favourable to it.

On the 17th of december he tranſplanted ſome roots which meaſured four inches in circumference. The 19th he tranſplanted a bed of ſeedlings out of the garden, fine ſtrong plants, they had been ſown the beginning of april, and had been cut down when in full flower. They were ſet in rows, twelve inches aſunder.

In 1788 at the beginning of april, upon the ſame piece of land, he ſowed the ſeed ſaved laſt year, in drills twelve inches aſunder; and in the midſt of it four rows of Lucern ſeed, at the ſame diſtances, in order to aſcertain their comparative value. He mowed the crop this firſt year to feed weaned calves: the food was good, but the produce trifling.

In june 1789 Le Blanc's Medick was in bloſſom before the Lucern, and much fuller of flower. Both the tranſplanted and ſown flowered luxuriantly: he ſaved it for ſeed, but it produced a very ſmall quantity: in november he dreſſed it with aſhes.

May the 26th 1790, he cut a ſquare yard of Lucern, and an equal meaſure of the Medick adjoining; the Lucern was talleſt, and appeared the larger bundle, but upon weighing them, the Lucern was three pounds three quarters, the Medick four pounds and a quarter. The crop of Medick was very fine, and had the appearance of having been ſown broad-caſt, the intervals being ſo filled up, that the drills could not be diſtinguiſhed, whereas the rows of the Lucern were very apparent.

The 2d of june he began to cut it for ſoiling eleven cart horſes, a large tumbrel load every day: it was not in flower, nor arrived at its full growth, but he cut it ſo early to prevent any graſs ſeeding in it. The five roods laſted the eleven horſes fourteen days: it was excellent food, and the horſe-keeper acknowledged it to be heartier than tares. The plants raiſed from ſeed are better than the tranſplanted ones.

He afterwards let it ſtand for ſeed, which being a very unequal crop, and ripening at different times, he gathered by hand, at the end of ſeptember and the firſt week in october: the quantity of it was very inconſiderable, and being very ſmall, it was troubleſome to threſh and clean it.

Mr. Young remarks upon this very ſatisfactory account of the introduction of a new plant into culture, that may bid fair to rival Lucern itſelf, that Mr. Le Blanc's farm at Cavenham being on a poor blowing ſand, he has very happily fixed on a plant which appears to thrive better on ſuch ſand than in richer ſoils. Mr. Young tried it in moiſt loams, worth 15s. an acre, but never could get the plants to do ſo well as on the pooreſt ſands[a].

8. *Hop-Medick.*

This plant has been much ſown of late years for ſheep feed in open fields, where it is a conſiderable improvement, firſt for the ſweet food, and then to help the land by ploughing it in getting a good crop of wheat after it on indifferent ſoils. Mr. Zappa of Milan, ſays that it likes deep ground, rich and expoſed to the ſun, multiplies very well from the ſeed, grows chiefly in the ſpring, flowering at the beginning of may (in the Milaneſe) and ripening the ſeed at the beginning of june; it grows but little towards the end of ſummer and in autumn. It is cut with Poa trivialis, fifteen inches high, but is naturally procumbent. It is very nutritious, and increaſes milk in cattle[b]. It is cultivated under the name of *Trefoil* or *Black Nonſuch*, and it ſeems as if ſome of the *Trifolia* or genuine Trefoils would anſwer the purpoſe of the farmer as well as this Medick, which has uſurped the name, to the excluſion of all others.

The Earl of Orford obſerved two luxuriant patches of it left untouched in the month of may, in a field of various graſſes, eaten bare by a flock of ſheep indifferently kept[c]. He might have obſerved the ſame of White Dutch Clover, or any other plant, however valuable, when run up to ſeed. But ſheep prefer a ſhort ſweet bite of natural graſs, though almoſt bare, to any thing elſe.

The ſeed of this plant falls ſo readily, that great loſs enſues from moving it, and in threſhing the leaſt ſtroke clears it. It is a good way therefore to threſh it in the field on a cloth, which is moved to the ſeed, and not the ſeed to the cloth[d].]

9. *Sea Medick.*

This plant is propagated by ſeeds, ſown upon a warm border of dry ſoil in the ſpring, where the plants are deſigned to remain; when the plants are come up, two or three of them may be tranſplanted into ſmall pots, to be ſheltered in winter, becauſe in very ſevere froſt, thoſe which are in the open air are frequently deſtroyed; though it will endure the cold of our ordinary winters, in a dry ſoil and ſheltered ſituation. The remaining plants require only to be thinned and kept clean. It may alſo be increaſed by cuttings, planted in june or july in a ſhady border, covering

[a] Young's tour. 1. 277. [b] Id. 6. 49.
[c] Id. 16. 48. [d] Id. 20. 508.

them close with a glass to exclude the external air: they will take root in about six weeks, and may then be either planted in a warm border or in pots, and treated in the same way as the seedling plants.

10. *Variable Medick.*

Some of the varieties are common in flower-gardens among other annuals under the names of *Snails* and *Hedge-hogs*, from the singular form of their seed-vessels. They are propagated by seeds sown in the middle of april, where they are to remain; they require no culture but to be thinned, and kept clean.

[The variety called Heart Trefoil or Heart Clover, but more properly Heart Medick or Spotted Medick, is frequently very luxuriant among Lucern, Saintfoin and Trefoil, and might be cultivated for the same purpose as the latter, but on account of its hairiness and the roughness of the seeds, it should be cut or pastured when young.

7. Leptoſpermum arachnoideum.
Smith in Linn. tranſ. 3. 263.
L. arachnoides. *Gærtn.* 1. 174. *t.* 35.
Leaves awl-ſhaped pungent, branchlets rough-haired, calyxes and teeth villoſe.

8. Leptoſpermum juniperinum.
Smith in Linn. tranſ. 3. 263.
Leaves linear-lanceolate pungent, branchlets ſilky, calyxes ſmooth, teeth membranaceous coloured naked.

9. Leptoſpermum baccatum.
Smith in Linn. tranſ. 3. 264.
Leaves linear-lanceolate pungent, branchlets rough-haired, calyxes ſmooth, teeth membranaceous coloured pubeſcent, capſule herried.

10. Leptoſpermum ambiguum.
Smith in Linn. tranſ. 3. 264.
Leaves linear recurved at the tip, calyxes ſmoothiſh, teeth leafy lanceolate naked, ſtamens longer than the corolla.

11. Leptoſpermum virgatum.
Forſt. gen. 48. *n.* 7.
Melaleuca virgata. *Lin. ſyſt.* 699. *ſuppl.* 343. *Forſt. ſer. auſtral. n.* 211.
Leaves oppoſite linear-lanceolate nerveleſs, umbels terminating.

DESCRIPTIONS, *&c.*

According to the obſervations of Dr. Smith, in his excellent treatiſe on the botanical characters of ſome plants of the natural order of Myrti, this genus is not naturally diſtinct from Metroſideros, the union of the filaments being all that diſtinguiſhes Melaleuca; for in the reſt of the fructification, as well as in habit, they agree. Accordingly the younger Linnæus, the two Forſters and Schreber unite them, and Juſſieu ſeems inclined to do ſo. But at the ſame time they confound with it the true genus of Leptoſpermum, than which nothing can be more diſtinct. Gærtner preſerves all three ſeparate; but ſeveral of his ſpecies of Metroſideros prove to be Melaleucæ.

1. This is a tree with a black trunk and white branches, whence the name Melaleuca. Leaves quite entire, almoſt veinleſs, petioled. Fructifications ſeſſile, agglutinated, ſcattered, below the leaves [a].

Loureiro deſcribes it as a middle-ſized tree, with a lofty flexuoſe trunk, and few, irregular, aſcending branches. Bark thick, pale, lamellated, ſeſſile and tough. Leaves flat, ſtraight, aſh-coloured, ſweet-ſmelling, hardiſh, ſcattered. Flowers white, ſeſſile, in long ſpikes towards the end, where it breaks out again into leaves. Bractes minute, ovate, acute. Calyx tubular, five-cleft; tube roundiſh, coriaceous, browniſh red; ſegments rounded, deciduous. Petals roundiſh, concave, longer than the calyx. Filaments about forty, in five or ſix bundles, unequal, placed upon the edge of the tube of the calyx. Anthers very ſmall, ovate. Germ three-lobed, ſurrounded by the calyx. Style equal to the ſtamens. Stigma thickiſh. Capſule roundiſh, opening at top, half-clothed with the truncated calyx, the ſegments having fallen off. Seeds many, very ſmall, compreſſed-angular.

Native of ſome parts of the Eaſt Indies and Cochinchina. From it is diſtilled the green aromatic oil called *Cajeput*, from *Caya Puti*, a white tree, which is the Malay name; whence Linnæus gave the name of Leucadendron to this ſpecies [b]. The oil has the taſte of Pepper-Mint, but ſtronger and colder, and a ſmell like turpentine; but it ſeldom comes to Europe unadulterated [c]. A decoction of the leaves is much uſed in Cochinchina, as a tonic, &c. The bark is very ſerviceable in caulking boats, covering houſes, &c [d].

2. This is unqueſtionably a diſtinct ſpecies from the preceding, with which the younger Linnæus confounded it. The leaves are much more thick and rigid, ſtraight, not falcated, nor ſo much pointed, of a lighter colour, with generally five, but ſometimes ſeven nerves. The footſtalks and youngeſt branches are downy, which is not the caſe in M. Leucadendron [e]. Gærtner remarks that the calyx is toothleſs. The flowers are pale yellowiſh green.

Native of New South Wales [f]. Introduced in 1775, by John Reinhold Forſter, L. L. D. [g]

3. This is nearly allied to M. ſuaveolens of Gærtner, with which its inflorescence and fructification almoſt entirely agree, but the leaves of that are much broader and elliptical. Thoſe of M. laurina have a great reſemblance to Daphne Laureola. Neither is this ſpecies at all aromatic, which M. ſuaveolens ſhould ſeem by its name to be. That comes from the hotter parts of New Holland, near Endeavour river. Specimens of this were brought to Sir Joſeph Banks from New South Wales by Governor Phillip.

4. This has altogether the habit of a Styphelia. The leaves are thick-ſet, twiſted, harſh, pungent and ſtriated, exactly as in ſeveral of that genus, and very ſlightly aromatic, ſo that it could hardly be taken for one of the Myrti, except by the fructification. The flowers are white, ſurrounding the lower part of the youngeſt branches in very ſhort cluſters. Calyx downy, with erect rigid ſpinous ſtriated permanent teeth. Petals ſmooth, membranous. Stamens twice as long as the calyx.

Gathered near Port Jackſon by Mr. David Burton.

5. The dried leaves taſte ſtrongly of coriander ſeeds. Flowers white, growing in ſhort cluſters round the branches, as in the following, but not quite ſo near the top. Its leaves differ widely from that ſpecies, being much ſmaller, not pungent nor rigid, but a little recurved. The young bark is of a ſilvery white.

6. Leaves numerous, ſcarcely an inch long, very narrow, though broader than thoſe of M. ericifolia, ſtiff and ſharp-pointed. Flowers ſmall, whitiſh, cluſtered round the tops of the youngeſt branches, ſo as to appear like little heads; but after flowering the branch is protruded beyond them, and the ripening capſules remain inveſting it in an annular manner. Gærtner's figure repreſents them in their moſt advanced ſtate, apparently bleached by expoſure to the air [h]. His deſcription is—Calyxes in the middle of the branchlets aggregate, ſuberoſe, ſpherical, toothleſs, very ſmooth, ſhining, ſnow-white, ſmalliſh. Capſules immerſed, three-celled.

7. This has much the habit of a *Dioſma*, in the leaves eſpecially, which are very diſtinctly marked, in a garden ſpecimen, with a row of reſinous ſpots on each ſide the midrib at the back; but theſe are leſs viſible in the wild plant. Flowers white, cluſtered about the lower part of the branches, in the form of a long ſpike. The footſtalk or claw of the united filaments is very long before it branches off, even thrice the length of the petals [i]. Calyx, according to Gærtner, ſubglobular, ſuberoſe, thick, five-toothed. Capſule immerſed, three-celled.

8. This is, in ſome reſpects, like M. nodoſa, but the leaves are lanceolate rather than linear, not above half ſo long as in that ſpecies, nor ſo rigid and pungent. The branches terminate in looſe ſpikes, from the top of which the branch is at length continued, as in the other ſpecies. Flowers ſeſſile, in alternate pairs, white. Claw of the ſtamens twice as long as the petals before the filaments branch off.—Sent from Port Jackſon by Mr. David Burton.

9. This is a large tree, the bark of which is very thick and ſpongy, ſerving the purpoſe of tinder. The branches are clothed with tapering glaucous leaves, thrice as long as in the laſt ſpecies, and from the ſummits ſpring ſeveral young branches, let with a ſeries

[a] Linn. mant. [b] Smith. [c] Loureiro. [d] Smith. [e] Id. [f] Hort. kew. [g] Smith. [h] Id.

of oppoſite ſeſſile ſolitary white flowers, not, as in that, in pairs ranged alternately, beyond which the branch is ſoon protruded. The eſſential character however of the ſpecies conſiſts in the filaments, which are very long, being pinnated, or ranged with ſtamens on each ſide, more or leſs regularly, from near the baſe to the ſummit. The leaves have a flavour like nutmeg.

10. Flowers purple, ranged along the branches of a year or two old, in little ſhort oppoſite ſpikes; which however ſoon prove to be real branches by the leaves ſhooting out at their ends, this lateral mode of inflorescence being common to almoſt the whole genus, M. laurina and ſquarroſa only having axillary branching flower-ſtalks; and no Melaleuca having been yet ſeen with terminating flowers.

The teeth of the calyx in this are permanent, and the whole of that part, as well as the back of the leaves, abounds with a fragrant eſſential oil, lodged in pellucid prominent dots. Mr. Fairbairn preſented flowering ſpecimens of this ſpecies to the Linnæan Society from Cheliea garden.

11. The flowers grow in a cylindrical form round the branches, and have ſome reſemblance to thoſe of *Metroſideros lanceolata*, commonly called *citrina*, occaſioned by the radiated crimſon filaments projecting in every direction. The claws of thoſe filaments are very long, linear, and of a dull yelloviſh hue like the petals.

It is the moſt beautiful of the genus, is plentiful in the Engliſh gardens, and was generally taken for an Hypericum, till it produced its elegant flowers. It grows in ſwampy grounds, and is found, like all here deſcribed, except the firſt, in New South Wales [a].

LEPTOSPERMUM.

Deſcription, &c.

When that part of the Dictionary was printed in which this genus ſhould regularly have ſtood, Dr. Smith's valuable obſervations on it were not publiſhed; they are therefore added here, rather than be wholly omitted, or reſerved for a diſtant appendix.

To this genus naturally belong many ſhrubs, which were referred by Dr. Solander to *Philadelphus*. Forſter confounded with them, under the name of *Leptoſpermum*, another moſt diſtinct genus, the *Metroſideros* of Banks and Solander. Gærtner firſt ſeparated all theſe, and really underſtood this genus, though he did not point out the genuine eſſential character, the capitate ſtigma, which, as well as the ſhortneſs of the ſtamens, clearly diſtinguiſhes it from *Metroſideros*. With *Philadelphus* it has no reſemblance in habit, nor ſcarcely any botanical characters in common. *Philadelphus* is clearly and ſtrikingly diſtinguiſhed by its more or leſs deeply quadrifid ſtyle, and ſimple ſtigmas, without adverting to the broad baſe of the petals, or the differences pointed out by Gærtner in the fruit.

The younger Linnæus and Schreber have confounded *Leptoſpermum* as well as *Metroſideros*, with *Melaleuca*, with which the latter only has any great natural affinity. Dr. George Forſter has fallen into the ſame error in his Prodromus.

Many of the ſpecies are to be ſeen in the Engliſh gardens, and ſeveral have often flowered. There are other ſpecies in the gardens, which Dr. Smith had not yet ſeen in ſufficient perfection to diſcriminate them [b].

1. This is a ſmall tree or ſhrub, ſometimes growing to a moderate height, and generally bare on the lower part, with a number of ſmall branches growing cloſe together towards the top; the younger ones ſilky. Leaves ſmall and pointed, like thoſe of the Myrtle; alternate, ſcattered, ſubſeſſile, quite entire, ſpreading, flat, even, dotted, dark green above, pale underneath. Flowers ſolitary, terminating, ſeſſile at the ends of the twigs, white, the ſize of thoſe of the Cherry. Bractes roundiſh, imbricate, concave, deciduous, ſurrounding and covering the calyx up to the middle. Calyx hemiſpherical: teeth ovate, concave, alternate with the petals, white within, red without, deciduous. Petals white, three times as long as the calyx. Filaments about twenty or twenty-four, ſhorter by half than the petals, inſerted in a ſingle row into the margin of the calyx. Anthers twin, roundiſh. Capſule hemiſpherical, umbilicated with the calyx, plano-convex above, excavated at top, five-ſtreaked, five-celled, five-valved, opening at top. Seeds many, very ſmall, linear, cylindric, extremely ſlender [c].

It grows commonly in dry places near the ſhores, in New Zealand. The underwood in Adventure bay, Van Diemen's land, chiefly conſiſts of this ſhrub.

The leaves were uſed by Captain Cook's ſhips crews as tea, whence they named it the Tea plant. The leaves have a very agreeable bitter flavour, with a pleaſant ſmell, when freſh; but loſe ſomething of both, when dry. If the infuſion was made ſtrong, it proved emetic to ſome, in the ſame manner as green tea. It was alſo uſed with ſpruce leaves, in equal quantity, to correct their aſtringency in brewing beer from them; and they rendered the beer exceedingly palatable [d].

This is the moſt commonly cultivated ſpecies in England, and flowers continually. Dr. Smith received it from the garden of Meſſrs. Lee and Kennedy, by the name of *Philadelphus floribundus*, along with three other ſpecimens, which he ſuſpects to be varieties of this. They were called *P. rubricaulis*, *P. rubriflorus*, and the original *P. aromaticus* [e].

This is called in the Kew catalogue *Philadelphus ſcoparius linifolius*, or narrow-leaved Philadelphus.

β. Is called there *Ph. ſcoparius myrtifolius*, or Myrtle-leaved Philadelphus. It was introduced into that garden in 1772, and flowers in June and July. This is a very ſlight variety, according to Dr. Smith, with ſhorter and broader leaves. It is however the *Lept. ſquarroſum* of Gærtner; of which he ſays the calyx is cloſely united with the capſule, and terminated by an unequal repand toothleſs margin: the capſules ſubglobular, flatted a little, umbilicate, five-celled, five-valved: the ſeeds linear, very numerous, ferruginous.

2. Dr. Smith, not having ſettled this ſpecies, omits it. It was obſerved in New Zealand by the Right Honorable Sir Joſeph Banks, and was introduced into the Kew garden in 1772. It flowers there in July and auguſt [f].

3. The flowers appear to be of a fine yellow in the dried ſpecimens.

4. The flowers ſeem to be white, and generally grow two together on ſhort flower-ſtalks, which are ſilky like the calyx.

5. This ſpecies varies with ſmooth and downy leaves; and the calyx is ſometimes merely ſilky, ſometimes clothed with long and thick projecting down.

Some varieties of it are in the gardens; eſpecially β of *Hort. Kew.* which has ſmall downy twiſted leaves, with a little recurved point; and is commonly called *Philadelphus pubeſcens*. It may be a diſtinct ſpecies [g].

Introduced in 1774, by Tobias Furneaux, Eſq. It flowers in June and July [h].

6. Of this Dr. Smith, having only one ſpecimen, and not having ſeen it alive, ſays no more than it is very diſtinct.

7. Of this alſo he has but a ſingle ſpecimen, which agrees well with Gærtner's figure, and the original ſpecimen at Sir Joſeph Banks's [i].

Capſule, according to Gærtner, half-inferior, covered as with a bark with the very thin woolly five-toothed calyx, globular, flatted a little, five-celled, five-valved. Receptacle a globular tubercle at the inner angle of each cell, faſtened to the axis of the fruit. Seeds very numerous, ſmall, oblong, thickening outwards, angular, ferruginous.

8. Dr. Smith has not had an opportunity of obſerving the flowers freſh. Mr. Fairbairn gave it him under the name of *Philadelphus dioſmifolius*.

9. This is a low depreſſed ſhrub. The flowers ſeem to be yellow, and by the appearance of the dried fruit it muſt be very pulpy.

10. This is the only ſpecies that has the ſtamens longer than the corolla, which is a character of *Metroſideros*; but as it differs from that genus, and agrees with *Leptoſpermum*, in the much more important

[a] Forſter, edcul. [b] Cook's 2d voy. 1. 99 to 101. & 3d 1. 108.
[c] Smith. [d] Hort. kew. [e] Smith. [f] Hort. kew.
[g] Smith. [h] Hort. kew.

character of the capitate ſtigma, as well as in habit, Dr. Smith does not heſitate to refer it to this. The flowers are white, and appeared magnificently in the garden of George Hibbert, Eſq.

Dr. Smith received all theſe ſpecies (except the ſecond) from New South Wales[1].

11. The under ſurface of the leaves is covered with dark reſinous ſpots[2].

Perhaps, ſays Dr. Smith, this ought to be added to the liſt of known ſpecies, but the two ſpecimens in the Linnæan herbarium are ſcarcely ſufficient to ſatisfy his doubts. The ſtamens ſeem to be regularly ten. If the fruit therefore be one-celled or two-celled, it may be an *Imbricaria*, with double the number of ſtamens. If the capſules ſhould be found to have three or four cells, it may be a decandrous *Baeckia*; with which genus its oppoſite leaves, as well as the ſize and appearance of the flowers agree; whereas the Leptoſpermums have alternate leaves. It muſt be left for future conſideration[3]. In the mean time it may ſtand here.

For the reaſon given above reſpecting Leptoſpermum, *I have added*

FABRICIA. (*So named from* Fabricius.)

Gærtn. t. 35.

Claſſ. 12. 1. Icoſandria Monogynia.

Nat. order of *Myrti* Juſſ.

ESSENTIAL CHARACTER.

Calyx five-cleft, half ſuperior. *Pet.* five, ſeſſile. *Stigma* capitate. *Capſ.* many-celled. *Seeds* winged.

SPECIES.

1. Fabricia myrtifolia.

Gærtn. fruct. 1. 175. *Smith in Linn. tranſ.* 3. 265. *Calycine teeth nearly orbicular, capſules ten-celled.*

2. Fabricia lævigata.

Gærtn. fruct. 1. 175. *Smith in Linn. tranſ.* 3. 265. *Leaves obovate, calycine teeth triangular, capſules eight-celled.*

DESCRIPTIONS, *&c.*

The numerous cells of the fruit, from eight to ten, and eſpecially the winged ſeeds, ſufficiently diſtinguiſh this genus from *Leptoſpermum*, to which it is next akin.

1. This ſpecies is twice as large as the ſecond in all its parts. Calyx hemiſpherical, with the teeth nearly orbicular. Petals rounded, concave, ſeſſile or without any claw. Capſule covered to the middle by the calyx, which becomes toothleſs, thick, aromatic; it is umbilicate, coriaceous, ten-celled, ten-valved. Receptacle central, globular, ten-grooved. Seed in each cell one or two, ſmall, compreſſed, brown, terminated by a large membranaceous wing. It was named *Philadelphus myrtifolius* by Solander.

2. Leaves alternate, obovate, ſmooth, very obſcurely three-nerved or five-nerved, of a light glaucous green. Teeth of the calyx triangular. Capſules axillary, ſeſſile, eight-celled. In each cell from five to eight ſmall winged ſeeds. Dr. Smith has received it from New South Wales, and it is plentiful in the gardens about London, but has never yet flowered.

PROPAGATION AND CULTURE.

All theſe plants muſt be kept in the dry Stove or glaſs-caſe, and may be increaſed by cuttings.

MELAMPODIUM. (*From* μελας, *black, and* πους, *a foot.*)

Lin. gen. n. 989. *Reich. n.* 1072. *Schreb. n.* 1338. *Gærtn. t.* 169. *Juſſ.* 188.

Claſſ. 19. 4. Syngeneſia Polygamia Neceſſaria.

Nat. order of *Compoſitæ Diſcoideæ. Corymbiferæ.* Juſſ.

GENERIC CHARACTER.

CAL. *Common* five-leaved, flat: *leaflets* ſubovate, the length of the flower, ſpreading very much.

COR. *Compound* radiated. *Corollets* hermaphrodite in the diſk: *Female* about five in the ray.

Proper of the Hermaphrodite one-petalled, funnel-form, five-toothed, erect:—of the Female, ligulate, ovate, entire or three-toothed.

STAM. in the Hermaphrodites: *Filaments* five, very ſmall. *Anther* cylindric, tubular.

PIST. in the Hermaphrodites: *Germ* very ſmall. *Style* briſtle-ſhaped, the length of the corolla. *Stigma* obſolete.—In the Females: *Germ* ſubovate, compreſſed, with rugged ſides, the top flat and membranaceous. *Style* very ſhort.

PER. *Calyx* unchanged.

SEEDS in the Hermaphrodites none: in the Females ſolitary, obovate, compreſſed, four-cornered, prickly at the ſides, crowned with a heart-ſhaped, involuted, converging calycle.

REC. chaffy, conical: *chaffs* lanceolate, coloured, the length of the florets.

ESSENTIAL CHARACTER.

Cal. five-leaved. *Recept.* chaffy, conical. *Down* one-leafed, involuted, converging.]

SPECIES.

1. Melampodium americanum.

Lin. ſpec. 1303. *ſyſt.* 790. *Reich.* 3. 923. *hort. cliff.* 425. *Gærtn. fruct.* 2. 436.

Calendula decumbens. *Mill. dict. n.* 9.

Caltha americana. *Houſt. reliqu.* 9. *t.* 21.

Stem upright, leaves ſublinear with one tooth on each ſide.

[2. Melampodium auſtrale.

Lin. ſpec. 1303. *ſyſt.* 790. *Reich.* 3. 923. *Loeſl. it.* 268.

Stem decumbent, leaves oval ſerrate.

3. Melampodium humile.

Swartz prodr. 114. *Ait. hort. kew.* 3. 269

Stem upright, leaves lyrate-toothed ſeſſile.

DESCRIPTIONS, *&c.*

1. Stems many, round, herbaceous, villoſe, procumbent. Leaves oppoſite, an inch and half long, and an inch broad, uſually divided into five ſegments, but ſometimes entire, hairy on both ſides, but chiefly at the back, where they are alſo hoary. Peduncles axillary, one-flowered. Calyx ſingle, compoſed of five broad mucronate hirſute ſegments. Corolla yellow. A crown of ſhortiſh ſeeds, covered with a rough bark ſucceeds radial florets[4].

Mr. Miller deſcribes the leaves as long, narrow, and indented on their edges in two or three places oppoſite to each other, ſo as to appear like three, five, or ſeven lobes. Peduncles long and naked, terminated by a ſingle yellow flower, about the ſize of the Field Daiſy. [Miller's deſcription of the leaves agrees with Houſtoun's figure: but Linneus's ſpecific character does not agree either with that or his deſcription.

According to Gærtner, there are about ten female florets in the ray. Receptacle flat: chaffs oblong, blunt, membranaceous, the inner ones gradually longer, ſo that the diſk of the flower appears to be conical. Seeds obovate, flatted on both ſides, brown; the back arched, ſtriated, the belly curved and narrowed to an edge, the ſides flat, rugged with tubercles. Crown cotyloid, ſtanding obliquely on the top of the ſeed, pale ſtraw-coloured, formed of a lamina, which when ripe becomes ſomewhat cartilaginous, one-leafed, obcordate; the edges are bent in ſo as to form two grooves within, or a cleft along the middle divided into two ſwelling lips.

Found by Houſtoun near La Vera Cruz, in ſandy ſoil, in the year 1731, flowering in the month of march, and bearing ripe ſeed[5], which he ſent to Mr. Miller, who raiſed the plants in Cheſſea garden.

2. Found by Loefling in South America. Forſkahl aſcribes hooked hairs to the ſeeds[6].

3. Found in Jamaica and St. Domingo by Swartz. Introduced in 1782, by Mr. Gilbert Alexander. It flowers from june to october[4].

Theſe are all annual plants.]

PROPAGATION AND CULTURE.

Sow the ſeeds in the ſpring on a hot-bed, and when the plants are fit to remove, put them into pots filled with light ſandy earth, and plunge them into the tanpit, ſhading them from the ſun, giving them air in warm weather, and treating them as other tender plants from the ſame countries.

Melampyro affinis ſ. cognata. See *Acanthus* and *Barleria.*

Flowers directed the ſame way lateral, leaves in diſtant pairs, corollas gaping wide.

DESCRIPTIONS, *&c.*

1. The whole plant is nearly ſmooth; extremely branched; branches oppoſite. Leaves oppoſite, ſeſſile, linear but tapering to a point; thoſe beneath the branches reflex, on the branches parallel. Flowers in cloſely imbricated ſpikes, forming heads, terminating the ſtem and branches. Bracteal leaves large, purpliſh, finely toothed, the middle tooth lengthened into a long reflex horn, the upper ones with ſhort horns, but none without: theſe bractes being folded at the back, and cloſely preſſed together at the edges, form a kind of ſquare, with concave ſides, the horns being at the angles. Flowers reddiſh. Others ſay yellow, and white. According to Relhan, the helmet is purpliſh or white, with a yellow edge: Pollich aſcribes the ſame colours to it; and adds, that the beard or lower lip is yellowiſh within, and ſtreaked with purpliſh lines on the outſide. Villars ſays that the flowers are red or white. Krocker, that the corolla is variouſly coloured, but that the beard and inſide of the throat are commonly yellow, and that the whole varies to white. Mr. Woodward remarks, that he has never obſerved the flowers to be yellow, though he has ſeen thouſands of plants in Ripton and other woods in Huntingdonſhire. In the autumn they grow eighteen inches or two feet high; and where there are numbers together, the numerous diverging branches are ſo entangled that it is very difficult to extricate them[a]. It is common in the woods of Bedfordſhire, and in Madingley and Kingſton woods, Cambridgeſhire. Found among corn in Walton-field near Wakefield, Yorkſhire, by Dr. Richardſon. Braybrook wood, Newton and Yarwell in Northamptonſhire. Ray obſerved it in mountainous woods near Geneva; and it is found in many other parts of the continent. It flowers in June and July.

2. Stem upright, ſlightly hairy, branched. Leaves oppoſite, lanceolate, lengthened to a point, nearly ſeſſile, ſlightly downy. Flowers in an oval head, with each a long lanceolate purpliſh bractle, pinnatifid with ſetaceous teeth at the baſe, entire upwards[b]. Corolla yellow and duſky purple[c]. Capſule like that of the fourth ſpecies, but more gibbous, and when open bifid at top. Seeds larger by half, pale yellow, ſhining, with a thick, ſungoſe, white beak[d]. Theſe ſeeds, when ground with corn, give a bitterneſs and a grayiſh caſt to the bread, but do not render it unwholeſome[e].

This is a weed in corn in many parts of Europe, among wheat in the more ſouthern parts, and among

[a] Woodw. MS. [b] M. [c] Withering. [d] Gærtner. [e] Linn. ſuec.

rie in the northern. Found alſo in Japan. In England it is not very common. Mr. James Sherard found it near Lycham in Norfolk; Mr. Woodward and Mr. Crowe near Norwich. Ray did not know that it was a native of England, when he publiſhed his hiſtory.

3. Root ſmall. Stem a foot and half high, upright, brachiate, four-cornered. Leaves either entire and ovate-acuminate, or ſomewhat ſagittate, eared and toothed at the baſe, rough, hirſute beneath, with hiſpid edges; petiole ſhort, thick and hirſute; the branches and leaves are very diſtant. Flowers ſingle or two together in the axils of oppoſite braſtes, not forming a perfect ſpike. Bractes blue-violet, laciniated at the baſe or toothed, woolly underneath and not blue; the upper ones blue on both ſides. The plant is readily known by this *coma* or knot of barren bractes. Corolla herbaceous-yellow, with the origin of the throat and gape deeper yellow; the tube purple and curved inwards; lower lip trifid, more lengthened out than in the other ſpecies, orange-coloured. Anthers bearded at the baſe. Calyx coloured, woolly, on a ſhort petiole[†].

Linnæus ſeems ſtruck with the beauty of the plant, and the ſplendour of the flowers. "Coma foliorum "violacea, ſubtus lucente fulvo florum colore, lucos "umbroſos ita exhilarat hæc planta, ac ſi aulam ipſius "Floræ aut Auroræ intrares." He remarks alſo that it is not a native either of England, or of ſeveral provinces of Sweden[*]. It is frequent in Upland and Scania, Denmark, Switzerland, Carniola, Auſtria, Sileſia, Dauphiné, &c. Ray found it between Grenoble and the Grande Chartreuſe. It flowers in july and auguſt.

4. Leaves lanceolate, greatly tapering towards the point, all ſerrated, but the ſerratures extremely fine, and the edges of the leaves being rather turned back, they are not very readily ſeen. Stem feeble, cylindrical towards the bottom, four-cornered upwards. Calyx purpliſh without; ſegments with minute ſtiff briſtles along the edge; the two upper longer. Corolla full yellow, very much compreſſed; the notch in the upper lip but barely perceptible; lower lip with two orange-coloured riſing plaits; tube ſtraw-coloured. Filaments ſupporting what appears a ſingle anther, which is ovate, compreſſed, hairy at the edges, and opening at the front edge, diviſible into four portions, but as readily breaking in any other direction; after flowering ſeparating into two or four parts. Style corresponding to the bend of the upper lip, riſing over the anther, and preſenting its ſummit to the opening, whence the pollen eſcapes. Seed-veſſel a yellow glandular ſubſtance at the baſe on the fore part, doubled down, and ſo briſtle as not to admit being ſtraightened[‡]. It is thus deſcribed by Gærtner. Capſule ovate, attenuated into a blunt beak, compreſſed, with a longitudinal groove on both ſides, without brown, within ſilky white: partition very narrow, almoſt obſolete. Seed ſolitary, ovate-oblong, ſmooth, whitiſh, ſomewhat ſhining, elongated at bottom into an umbilical corneal ſpongy beak.

This ſpecies is thus accurately deſcribed by Pollich. Root hardiſh, whitiſh, fibrous. Stem upright, or decumbent, erect towards the top, obſcurely four-cornered, ſlightly pubeſcent, reddiſh green. Branches oppoſite. Leaves oppoſite, ſeſſile, linear-lanceolate, bluntiſh, quite entire, bright green and ſlightly pubeſcent above, netted underneath; the larger ones more than two inches long, and three lines wide, purpliſh at the baſe; the floral leaves ſmaller and a little reflex, with two or four ſharp toothlets at the baſe. Flowers ſolitary, ſubſeſſile by pairs in the axils of the leaves, chiefly on one ſide and forming a one ſided ſpike. Bractes a pair of leaves to each pair of flowers. Theſe are a little more than two lines in diameter, and almoſt eight lines in length. Calyx purpliſh-green, ſmooth; teeth lanceolate, acuminate, the upper ones ſomewhat reflex, and leſs deeply divided. Corolla yellow; tube compreſſed, triangular, white at the baſe and ſmooth; helmet blunt, ſlightly cleven at the top, the edge a little turned back, pubeſcent within; beard blunt with three blunt toothlets, and two ſmall ſmooth elevations at the throat. Anthers green and yellow, converging above, villoſe at the baſe and edge. Germ ovate, compreſſed ſmooth, with a roundiſh yellow nectary at the baſe of it. Style white, ſmooth, bent in at top, ſtanding out a little from the cleft of the helmet; ſtigma blunt, white. Pollich ſeems to regard this and the *ſylvaticum* as one ſpecies.

Mr. Woodward informs us, that our ſpecies ſo frequent in the woods of Norfolk and Suffolk, and other parts of the kingdom, in a clayey ſoil, was looked upon to be the *M. ſylvaticum* of Linnæus; but from a doubt which occurred to him in the ſpring of the year 1785, he was induced to believe it to be *M. pratenſe*, and that *ſylvaticum* was unknown in England, at leaſt in thoſe counties. This doubt was afterwards confirmed by Dr. Smith's aſſuring him, that the ſpecimen of M. pratenſe in the Linnean herbarium correſponded exactly with our plant. He believes however that the *ſylvaticum* of Linnæus is merely a variety; and ſuch was the opinion of Linnæus himſelf in his early writings. In Flora Lapponica 194. he gives *M. pratenſe*, which is ours, as the ſpecies, and *ſylvaticum* as the variety; thus diſtinguiſhing them: in the firſt, the ſtem is more upright, the leaves more upright and converging, the corolla white but becoming yellow towards the lips, the mouth or the lips cloſed, and it inhabits meadows and drier places: in the ſecond, the ſtem is more nodding, the leaves altogether ſpreading, the corolla entirely fulvous, and much ſhorter than in the preceding, the mouth open and gaping, and it inhabits woods and buſhy places.

If Melampyrum latifolium flore albo, labio inferiore duabus maculis luteis diſtincto. *Tourn. par. Raii ſyn. ed.* 3. *286. 2*. be *M. pratenſe*; and M. ſylvaticum flore luteo, &c. *Bauh. hiſt. Raii ſyn.* *286. 2. be *M. ſylvaticum*; then Dillenius regarded the former as a variety only of the latter.

Other authors diſtinguiſh them. Haller thus deſcribes his n. 308. which is Linneus's *Mel. pratenſe*. Stem weak, a long ſpan in height. Leaves very long lanceolate, the loweſt entire, the middle ones having a few large teeth at the baſe, the uppermoſt trifid, haſtate, with reflex hooks. Flowers in pairs, as in the next ſpecies, ſeſſile in the axils, all on one ſide. Corolla white; tube long, ſlender, wrinkled, widening in front. Gape, like that of a fiſh, converging; helmet yellow; pale at the edge; lips converging; two riſings divide the beard into three very ſhort teeth: theſe riſings are deep yellow. Anthers glued together. Lightfoot's and Relhan's deſcriptions are chiefly taken from Haller. According to Krocker, it differs from *ſylvaticum* in having a ſmaller calyx, of a purpliſh green colour, conſtantly marked with purple lines and ſmooth: corolla compreſſed, bent upwards, ſmooth, cloſed, variegated yellow and red, or more often entirely yellow, with a white tube; beard purple on the outſide, trifid. Anthers converging, yellowiſh green, villoſe. Leaves parallel to the horizon, varying in their inciſions; the lower ones on ſhort petioles, ligulate; the uppermoſt jagged, haſtate, beneath veined and ſlightly pubeſcent. Stem upright or decumbent, obſcurely four-cornered, pubeſcent, from ſix inches to a foot in length.

Dr. Stokes remarks, that the lower lip of the corolla is ſtraight, not bent downwards as in *M. ſylvaticum*. Dr. Withering adds, that *M. pratenſe* has been frequently miſtaken for *ſylvaticum*, probably becauſe it generally grows in woods, or on the ſkirts of them; but this is not the only inſtance in which too much attention to a trivial name has been the occaſion of error.

It is an obſervation of Linneus's, that where this plant abounds, the butter is yellow and uncommonly good; that kine are very fond of it, though they reject the *avenæ*, that ſheep and goats eat it, and that horſes and ſwine refuſe it; that the latter however are very fond of the ſeeds.

5. According to Linneus, this differs thus from the preceding. Stem more nodding, leaves fully ſpreading, corolla only half as long, entirely yellow, and not with the tube white, mouth or opening between the lips gaping wide. But *M. pratenſe* has ſometimes the whole

[†] Krocker. [*] Fl. ſuec. [‡] Withering.

whole of the corolla yellow, so that colour, as usual, must not be too much trusted. Stem upright or nodding, weak, branched, leafy. Leaves very entire, all undivided, very long, lanceolate'.

Haller describes the stem as upright or nodding, weak, branched and leafy. Leaves quite entire, very long, lanceolate. Flowers in pairs, sessile in the axils, all pointing the same way, the whole of a deep yellow, gaping wide, the beard more deeply trifid; compared with the leaves three times less than in the preceding. Fruit ovate-conical, curved inwards.

Relhan describes the stems as square, reddish, smooth: leaves linear-lanceolate, veined, quite entire, smooth, almost sessile. Bractes jagged. Flowers in pairs, sessile, remote. Calyx coloured. Corolla yellow, gaping a little; lower lip convex, three-toothed.

According to Villars, it is smaller in all its parts, and the leaves are very narrow and entire, the flowers also are smaller, paler and open, the calyx is square at the base.

Krocker says, that this has a very small root; is lower in stature; the stem roundish, a span or half a foot in length, branched, villose, angular; leaves quite entire, linear-lanceolate, yellowish green; peduncles hirsute; the calyx has four raised streaks; corollas shorter by half, gaping wide, yellow all over; helm not compressed but roundish, smooth on the outside, bearded with yellow hairs within, emarginate and folded back at the edge; by which marks it may easily be distinguished: lower lip flat, trifid, yellow with red lines. Anthers sagittate, like those of Euphrasia, greenish yellow, bearded on one side, toothed at bottom. Capsule ovate-compressed, triangular, two-celled, with many testiculate seeds.

Native of many parts of Europe in woods. Much rarer than the preceding in England, if it differs from it, or if the true *sylvaticum* of foreign authors be found with us. Found at Wick Cliffs by Mr. Swayne. Stechworth, White-wood, and Hadley-wood in Cambridgeshire. In the way from Taymouth to Lord Breadalbane's cascade, and about Finlarig at the head of Loch-Tay.

All the species are annual. Leaves opposite. Flowers opposite, accompanied by bractes, forming a terminating spike.]

PROPAGATION AND CULTURE.

These plants are seldom cultivated in gardens. Some of them indeed are common weeds, but not noxious in England. The second sort grows very plentifully among corn in Flanders and other parts of the continent, and is said to make the bread dark, and to affect the head in the same manner with Darnel; but Ray affirms that he has often eaten this bread, without perceiving any disagreeable taste in it, and that it was not accounted unwholesome by the country people; Tabernæmontanus also declares, that he has often eaten it without harm, and that the bread in which it is mixed is even not unpleasant. It is a delicious food for cattle, and might be cultivated for fattening oxen.

The seeds of all these plants should be sown in the autumn soon after they are ripe, otherwise they seldom grow the first year. When the plants come up, weed them in the spring whilst young. As soon as they begin to show their flowers, cattle may be turned in upon a spare hurdled off; for if they are permitted to run over the whole field, they would trample down the crop, and destroy a great part of it.

The third sort makes a pretty appearance with its purple tops during the months of july and august, and deserves a place in the flower garden among other annuals.

DESCRIPTIONS, &c.

1. Flower-stalks from six to eight inches high, branching at top into three or four divisions, with two or three linear leaves below the flowers. Corolla of a dusky colour, rarely succeeded by seeds in England.

Native of Virginia and other parts of North America. [Cultivated by Mr. Miller in 1768. It flowers in june and july.

2. Native of North America. Introduced in 1770, by George W. Earl of Coventry. It flowers in june[a].

3. Root bulbous, oblong. Leaves radical, half a foot long, linear, acuminate, striated, attenuated into the petioles. Stem naked, a foot high, round, surrounded by a single, linear, short leaf. Flowers panicled: peduncles alternate, one-flowered, the lower

[1] Withering.

[a] Hort. kew.

peduncle longer, with alternate pedicele. Bractes lanceolate, ſeſſile, acuminate, at the baſe of each peduncle, coloured, very ſhort. Petals lanceolate, reflex, permanent, white. Nectary obconiate, bifid, faſtened to the baſe of the petals. Filaments awl-ſhaped, ſhorter by half than the corolla, and faſtened to it at the baſe of the nectary. Styles erect, awl-ſhaped. Capſule acuminate, with compreſſed valves. Seeds oblong, membranaceous, angular.

It differs from the firſt ſpecies in having the petals ſeſſile, and the filaments not rigid and permanent. The appearance however is quite the ſame with that [b]. Native of Siberia.

Willich is of opinion, that Gmelin's name belongs rather to Anthericum ramoſum.

4. Stem quite ſimple. Leaves embracing, ſheathing at bottom, the ſheath widening at top: there are four of them on the ſtem, the uppermoſt and loweſt very ſmall. Raceme terminating. Petals oval, with very ſhort claws. Stamens generally inſerted into the receptacle [c].

Native of the Cape of Good Hope. Introduced, according to the Kew Catalogue in 1788. Miller however ſeems to have cultivated it in 1768.

5. Root bulbous. Herb the ſtature of *Ornithogalum luteum*. Stem ſimple, upright, ſmooth and even. Stem-leaves three, longer than the ſtem. Peduncles terminating, commonly two; one one-flowered, the other two-flowered: floral leaves two, wider, ſhorter. Flowers ſhorter than the leaves, dark purple. Stamens and piſtils ſhorter than the corollas. Capſule triangular, ſmooth and even, the ſize of a Coffee ſeed.—Native of Tranquebar in the Eaſt Indies [d].

6. Stem ſix feet high, ſhrubby, round, ſlender, branched, procumbent, with ſhort ſcattered prickles. Root conſiſting of a bundle of oblong, fleſhy, reddiſh-brown tubers. Leaves linear, ſtellate-tern, quite entire, ſmooth, ſmalliſh, unequal. Flowers white, on one-flowered peduncles. Seeds roundiſh, very black, rugged, one or two of each only ripen.—Frequent in dry hedges in China and Cochinchina. It is allied to the preceding [e].

7. Stem half a foot high, leafy, ſubpubeſcent. Leaves alternate, ſeſſile, upright. Peduncles alternate, ſide-flowering, filiform, one-flowered, the length of the leaves. Flowers drooping. Petals narrow-lanceolate, purple, narrower at the baſe with the edge converging, and yellow. Stamens ſhort.—Found at the Cape of Good Hope by Thunberg [f] and Maſſon [g], and introduced by the latter in 1788 [h].

8. Leaves ſhorter than the ſtem. Petals white, lanceolate.—Found at the Cape of Good Hope by Thunberg.

9. Found at the Cape of Good Hope by Thunberg [i] and Maſſon. Introduced by the latter in 1788 [k].

10. Root globular, ſmooth. Stem none, or a finger's length, round, ſimple, ſheathed, ſtriated. Leaves three, alternate, ſheathing or cowled at the baſe, lanceolate-ſubulate, channelled, longer, diſtich, even, recurved. Spike an inch long, flexuoſe. Flowers alternate, ſomewhat remote, whitiſh, with the teeth black at the edge. It varies with white and purple corollas, with a black and purple edge, with a ſhorter and longer tube. It reſembles *M. capenſe*. The one-petalled corolla is not ſufficient to make this of a ſeparate genus, ſince the proportion of the tube varies in this and M. ſibiricum, and it may eaſily be divided by a needle.—Found at the Cape of Good Hope by Sparrmann [l], Thunberg and Maſſon. Introduced by the latter in 1788 [m].]

PROPAGATION AND CULTURE.

1, 2, 3. Plant the roots in a border of light earth, not too dry. They will produce their flowers, but ſeldom increaſe.

4, &c. Plant the roots in a border, covered in winter with a garden frame; and treat them in the ſame way as is directed for Ixia.

Leaves quite entire three-nerved lanceolate rugged.]

7. Melaſtoma holoſericea.
Lin. ſpec. 559. *ſyſt.* 404. *Reich.* 2. 286. *hort. cliff.* 162. 2. *Swartz obſ.* 176. *Vahl ecl.* 1. 42? *Plak. mant. t.* 250. *f.* 2. (Acinodendrum). *Breyn. cent.* 3. *t.* 2. & *f.* in *p.* 4. (Arbor racemoſa) *Mayer. bruſ.* 117.
Leaves entire three-nerved ſeſſile ovate acute villoſe-ſilky, racemes bracteate, branches two-parted, ſtem acutely quadrangular.

[8. Melaſtoma ſtrigoſa.
Lin. ſyſt. 404. *ſuppl.* 236.
Leaves quite entire three-nerved ſtrigoſe ovate, flowers ſolitary.

9. Melaſtoma ſeſſilifolia.
Lin. ſpec. 558. *ſyſt.* 404. *Reich.* 2. 286. *Brown. jam.* 219. 1. 24. *f.* 1. 2. *Plak. phyt. t.* 249. *f.* 2.
Leaves quite entire triple-nerved ſpatulate ſeſſile tomentoſe underneath.]

10. Melastoma malabathrica.
Lin. spec. 559. *Jacq. amer.* 2. 286. *f.* 254. *n.* 171. *Gaertn. fruct.* 2. 201. *Burm. zeyl.* 155. *t.* 73. *ind.* 104. *Forst. for. austral. n.* 193. *Rheed. mal.* 6. 87. *t.* 42. (Kelladi). *Rumph. amb.* 4. 137. *t.* 73. (Fragarius niger).
Leaves quite entire five-nerved lanceolate-ovate rugged.
11. Melastoma levigata.
Lin. spec. 559. *Jacq. amer.* 2. 287. *Gaertn. fruct.* 2. 204. *Swartz obs.* 176. *Brown. jam.* 219. *t.* *Sloan. jam.* 2. 140. *Raii dendr.* 26. (Grossularia).
Leaves quite entire five-nerved ovate-oblong levigated acuminated, even about the edge.
12. Melastoma dilcolor.
Lin. spec. 560. *Jacq. amer.* 130. *t.* 84. *pict.* 65. *t.* 125. *Plum. ic.* 142. *f.* 1. (M. procera. *Swartz*). *Sloan. jam.* 2. 86. *t.* 198. *f.* 1. (Grossularia). *Pluk. phyt. t.* 264. *f.* 4. (Arbor americana).
Leaves quite entire five-nerved oblong acuminate smooth and even at the edge, racemes cymed, flowers eight-stamened.
13. Melastoma octandra.
Lin. spec. 560. *Jacq. amer.* 204. *Reich.* 2. 287. *Osb. it.* 213.
Leaves quite entire three-nerved ovate smooth hispid at the edge.
14. Melastoma grossa.
Lin. syst. 404. *Suppl.* 236.
Leaves quite entire five-nerved subcordate rugged.
15. Melastoma crispata.
Lin. spec. 560. *Jacq. amer.* 204. *Reich.* 2. 288. *Rumph. amb.* 5. 66. *t.* 35. (Punis murenarum).
Leaves quite entire five-nerved in fours, branches curled.

Species from Swartz.

* *Ten-stamened, with three-nerved leaves.*

16. Melastoma procera.
Swartz prodr. 68. *Plum. ic.* 142. *f.* 1.
Stem arborescent, leaves three-nerved somewhat toothletted smooth, raceme terminating spikes simple erect, calyxes truncated.]
17. Melastoma patens.
Swartz prodr. 68.
M. umbellata. *Mill. dict. n.* 10.
Leaves three-nerved, somewhat toothletted cordate hirsute, raceme terminating patulous, flowers distinct twice-stamened.
18. Melastoma rigida.
Swartz prodr. 69.
Leaves three-nerved somewhat toothletted ovate subcordate rigid rugged behind, panicles terminating ferruginous-hirsute.
19. Melastoma quadrangularis.
Swartz prodr. 69.
Leaves three-nerved entire ovate-lanceolate smooth, nerves coloured, branches quadrangular, raceme straight, terminating.
20. Melastoma scandens.
Swartz prodr. 69.
Leaves three-nerved toothletted ovate acute smooth, raceme terminating, spikes mostly pointing one way, stem climbing.
21. Melastoma montana.
Swartz prodr. 69.
Leaves three-nerved toothletted oblong acute smoothish, raceme terminating with pallulous spikes, petals retuse, calyx truncate.
22. Melastoma trinervia.
Swartz prodr. 69.
Leaves three-nerved without any marginal nerve, oblong attenuated at the base and tip entire, smooth on both sides thinnish, racemes almost simple terminating.
23. Melastoma ramiflora.
Swartz prodr. 69.
Leaves three-nerved entire ovate-lanceolate somewhat rugged, branches flower-bearing, flowers peduncled somewhat clustered.

** *Ten-stamened, with triple-nerved leaves.*

24. Melastoma prasina.
Swartz prodr. 69.
M. levigata. *Aubl. guian.*
Leaves triple-nerved quite entire broad lanceolate ovate, panicle terminating spreading very much.

*** *Ten-stamened, with five-nerved leaves.*

25. Melastoma argentea.
Swartz prodr. 70. *Sloan. jam.* 2. 84. *t.* 199. *f.* 1. (Grossularia).
Leaves five-nerved somewhat toothletted ovate smooth, tomentose and white underneath, panicles terminating spreading.
26. Melastoma elata.
Swartz prodr. 70.
Leaves five-nerved serrate-toothletted oblong coriaceous, ferruginous-tomentose underneath, panicles terminating spreading, flowers sessile.
27. Melastoma Tamonea.
Swartz prodr. 70.
Tamonea guianensis. *Aubl. guian.* 441. *t.* 175.
Grossulariæ fructu arbor maxima. *Sloan. jam.* 2. 84. *Pluk. phyt. t.* 264. *f.* 4.
Leaves five-nerved oblong-lanceolate ovate entire, tomentose-hoary underneath, racemes compound terminating, racemelets brachiate, bradles in pairs under the flowers.
28. Melastoma albicans.
Swartz prodr. 70.—an, holosericea. *Vahl enl.* 1. 42.
Leaves five-nerved entire ovate acute smooth above, tomentose whitish-ferruginous underneath, racemes terminating erect, flowers clustered sessile.
29. Melastoma impetiolaris.
Swartz prodr. 70.
Leaves five-nerved toothletted subsessile oblong acuminate coriaceous tomentose-ferruginous underneath, panicles terminating and axillary erect.
30. Melastoma splendens.
Swartz prodr. 70. *Plum. ic.* 140.
Leaves five-nerved entire oblong acuminate smooth on both sides, shining above, panicles terminating erect.
31. Melastoma coriacea.
Swartz prodr. 70.
Leaves five-nerved cartilaginous-toothletted ovate wrinkled smooth coriaceous, branches and petioles strigose, branches of the panicle four-cornered.
32. Melastoma strigillosa.
Swartz prodr. 71.
Leaves five-nerved somewhat toothletted subcordate acuminate, strigose-hoary above tomentose underneath, racemes axillary solitary, flowers peduncled clustered.

**** *Eight-stamened, with three-nerved leaves.*

33. Melastoma fascicularis.
Swartz prodr. 71.
Leaves three-nerved entire ovate acute rugged, branches flower-bearing, flowers shortly peduncled clustered.
34. Melastoma angustifolia.
Swartz prodr. 71.
Leaves three-nerved linear-lanceolate entire hoary underneath, branches wand-like, panicles terminating, flowers erect.
35. Melastoma Micranthus.
Swartz prodr. 71.
Leaves three-nerved toothletted oblong acute furrowed, racemes axillary reclining, flowers acuminate.
36. Melastoma capillaris.
Swartz prodr. 71.
Leaves three-nerved somewhat toothletted broad-lanceolate attenuated smooth, peduncles capillary three-flowered axillary.
37. Melastoma rubens.
Swartz prodr. 71. *Brown. jam.* 219. *n.* 8.
Leaves three-nerved toothletted ovate-lanceolate acuminate very smooth, branches and petiolet coloured, racime terminating, flowers clustered dioecous.
38. Melastoma purpurascens.
Swartz prodr. 71.
Leaves three-nerved entire oblong acute striated very smooth, racemes lateral patulous, flowers distinct.
39. Melastoma glabrata.
Swartz prodr. 71.
Leaves three-nerved somewhat toothletted ovate acute smooth coriaceous, peduncles terminating solitary one-flowered.

40. Melastoma alpina.
Swartz prodr. 73.
Leaves three-nerved entire ovate coriaceous smooth, peduncles simply trichotomous, flowers diffuse.

41. Melastoma hirsuta.
Swartz prodr. 72.
Leaves three-nerved somewhat toothletted broad-lanceolate attenuated hirsute, peduncles axillary three-flowered divaricated.

42. Melastoma hirtella.
Swartz prodr. 72.
Leaves three-nerved hispid at the edge, peduncles very short axillary three-flowered.

43. Melastoma microphylla.
Swartz prodr. 72.
Leaves three-nerved somewhat toothletted ovate obtuse, hispid above, tomentose underneath, peduncles trifid axillary.

44. Melastoma tetrandra.
Swartz prodr. 72.
Leaves three-nerved entire oblong acuminate emarginate at the base smooth somewhat convex, raceme erect terminating, flowers four-stamened.

***** *Eight-stamened, with triple-nerved leaves.*

45. Melastoma virgata.
Swartz prodr. 72.
Leaves triple-nerved entire ovate lanceolate acuminate very smooth, branches flower-bearing, racemes decussated diffused scattered.

46. Melastoma Æleagnoides.
Swartz prodr. 72.
Leaves triple-nerved entire broad-lanceolate whitish-tomentose underneath, peduncles terminating trichotomous, flowers solitary.

****** *Eight-stamened, with five-nerved leaves.*

47. Melastoma umbrosa.
Swartz prodr. 72.
Leaves five-nerved toothletted broad-ovate acuminate rough-haired on both sides, branchlets flower-bearing, racemes dichotomous spreading, branches and petioles hirsute.

48. Melastoma pilosa.
Swartz prodr. 72.
Leaves five-nerved toothletted oblong acute hirsute underneath, racemes lateral hirsute.

49. Melastoma hispida.
Swartz prodr. 72.
Leaves five-nerved somewhat toothletted ovate acute, strigose-hirsute above, netted-tomentose underneath, panicles terminating divaricated.

50. Melastoma aquatica.
Swartz prodr. 73. *Aubl. guian.* 430. *t.* 169.
Leaves five-nerved cordate acute crenulate, rough-haired above, even underneath, panicles terminating trichotomous diffused.

From Forster.

51. Melastoma glabra.
Forst. flor. austral. n. 194.
Leaves quite entire three-nerved elliptic-lanceolate rugged, calyxes cut round.

From Vahl.

52. Melastoma grandiflora.
Vahl symb. 3. 59. *Aubl. guian.* 414. *t.* 160.
Leaves cordate five-nerved serrulate, both they and the stem rough-haired, peduncles bifid, five stamens barren.

* *Twelve-stamened.*

53. Melastoma calyptrata.
Vahl ecl. 1. 40.
Leaves elliptic-lanceolate attenuated three-nerved smooth obsoletely toothletted, flowers panicled.

** *Ten-stamened, with three-nerved leaves.*

54. Melastoma aromatica.
Vahl ecl. 1. 41.
Tibouchina aspera. *Aubl. guian.* 445. *t.* 177.
Leaves ovate stalked, somewhat hairy underneath, nerves and stem strigose, calyxes with imbricate bractes at the base.

55. Melastoma crenata.
Vahl ecl. 1. 41.
Hispid, leaves subcordate oblong crenate acuminate, racemes axillary few-flowered the length of the petiole.

56. Melastoma decussata.
Vahl ecl. 1. 42.
M. racemosa. *Aubl. guian.* 406. *t.* 156?
Leaves lanceolate-oblong serrulate ciliate very smooth above, spikes racemed two-parted, flowers clustered.

*** *Ten-stamened, with five-nerved leaves.*

57. Melastoma elegans.
Vahl ecl. 1. 44. *Aubl. guian.* 427. *t.* 164.
Hispid, leaves cordate unequally crenate-toothed, racemes in the forkings and terminating few-flowered.

58. Melastoma psyllophora.
Vahl ecl. 1. 45.
Tococa guianensis. *Aubl. guian.* 437. *t.* 174.
Leaves ovate attenuated toothletted ciliate, petioles hispid shuddery at the tip.

59. Melastoma capitata.
Vahl ecl. 1. 45.
Leaves broad lanceolate quite entire, heads terminating involucred, branches four-cornered, filaments appendicled.

*** *Eight-stamened, with three-nerved leaves.*

60. Melastoma triflora.
Vahl. ecl. 1. 46.
Leaves elliptic-lanceolate quite entire, branches petioles and calyxes strigose, flowers axillary subpedunculed in threes.

**** *Eight-stamened, with triple-nerved leaves.*

61. Melastoma acuminata.
Vahl ecl. 1. 47.
Leaves ovate outwardly toothletted acuminate hoary underneath, corymbs terminating fastigiate.

62. Melastoma verticillata.
Vahl ecl. 1. 47.
Leaves ovate oblong attenuated toothletted villose rugged above, racemes axillary, flowers in whorls.

63. Melastoma lateriflora.
Vahl ecl. 1. 48.
Leaves obovate acuminate setaceous-subserrate smooth, peduncles intrafoliaceous aggregate one-flowered.

***** *Eight-stamened, with five-nerved leaves.*

64. Melastoma coccinea.
Vahl ecl. 1. 48.
Leaves elliptic-ovate acuminate smooth quite entire, thyrse terminating, pedicules and pedicels knotted hispid.

65. Melastoma sessiliflora.
Vahl ecl. 1. 49.
Villose-subtomentose, leaves lanceolate-ovate toothletted subpetioled, flowers axillary sessile in a sort of whorl.

From Loureiro.

66. Melastoma septemnervia.
Lour. cochinch. 273. *ed. Willd.* 335.
Leaves seven-nerved quite entire lanceolate-ovate hispid.

67. Melastoma dodecandra.
Lour. cochinch. 274. *ed. Willd.* 336.
Leaves five-nerved quite entire smooth, flowers twelve-stamened.

DESCRIPTIONS, *&c.*

These are trees or shrubs. Leaves opposite, strongly nerved at the back. Flowers oppositely corymbed, panicled or spiked, axillary and terminating, sometimes (as in n. 3. 12. 33 to 50. 60 to 65.) four-petalled and eight-stamened with a four-celled fruit, Species 53. and 67. have twelve stamens. Calyx in most of the species contracted above the fruit, and prominent beyond it, in some equal to the truncated fruit and not contracted. The petals in some are appendicled on one side. Germ, according to Linnæus, wrapped up in the calyx: according to Jacquin subinferior;—to Gærtner, superior; or as Aublet says, sometimes inferior, sometimes superior. Aublet mentions some with a three-celled, others with a two-celled fruit, some with a capsular fruit divisible into valves, some with a calyx two-bracted on the outside, some with an herbaceous stem more

allied to Rhexia, one with five barren ſtamens, one with a ten-toothed calyx. This genus has now been augmented ſo much by modern diſcoveries, that it requires farther examination, and perhaps to be diſtinguiſhed into ſeveral genera. Fothergilla of Aublet belongs to this genus[a]. Melaſtoma is diſtinguiſhed from Rhexia principally by the fruit, which in the former is a berry, in the latter a capſule. Number is no criterion in this genus. Theſe trees are chiefly natives of the Weſt Indies; ſome few of the Eaſt Indies.]

1. This becomes a large tree, having many crooked branches, covered with a brown bark. Leaves ſmooth, entire, above five inches long, and two broad in the middle, with three deep veins running through them; both ſides are of a light green, the edges are ſharply indented, and they end in acute points. The fruit grows in looſe ſpikes at the end of the branches, is thinly placed in the ſpikes, and of a violet colour.

[Native of South America. It is an obſcure ſpecies. Sloane's plant, aſſigned to this by Linneus, belongs to M. argentea of Swartz[b], n. 25.

2. This was found in Surinam by Bartſch[c]. Mr. Miller has one under this name, but he refers to the third ſpecies, which is not this plant.

3. Stem ſhrubby, ſcarcely a fathom in height, branched, hirſute: branches erect, round, hirſute. Leaves larger, ſubdecuſſated, ovate, attenuated, blunt, toothletted, triple-nerved, rugged with papillas which terminate in a hair and are excavated underneath, hirſute-tomentoſe. Petioles long, looſe, round, thick, hirſute. Flowers axillary, very much cluſtered, ſeſſile, extremely minute, whitiſh red, eight-ſtamened. Calyx four-cleft, purple, hirſute, with the hinder ſegments awl-ſhaped, minute. Petals four, ſcarcely larger than the calyx, lanceolate, acute, ſpreading, white. Filaments eight longer than the corolla, knee-jointed. Anthers linear, acute. Germ inferior, covered by the calyx. Style columnar, thickiſh. Stigma blunt. Berry minute, roundiſh, ſurrounded and crowned by the calyx, hirſute, rufous, four-celled.—Native of the cooler mountains of Jamaica, flowering in november and december[d].

4. Stem ſhrubby, a fathom in height, hiſpid. Branches upright, hirſute, round; branchlets ferruginous-hiſpid. Leaves ovate or ovate-lanceolate, acuminate, toothletted, five-nerved, wrinkled, ſoft, very hirſute. Petioles longiſh, round, hirſute. Flowers axillary and terminating, largiſh: pedunckes very ſhort, aggregate, (three or four) hirſute. Calyx five-cleft, hirſute with blood-red hairs: ſegments ovate, augmented behind with linear, acute, erect, hirſute ſegments. Petals five, ovate, white. Filaments ten, inſerted into the calyx within, ſhort. Anthers oblong, bifid. Germ ovate. Style thick, round. Stigma blunt, concave. Berry cloathed and crowned by the calyx, hirſute, blue, five-celled.

It varies with a ſix-cleft calyx, ſix petals, twelve ſtamens, and a ſix-celled berry.

Native of the woody mountains of Jamaica, flowering in ſpring and autumn[e].

5. This is a ſtiffiſh ſhrub. Leaves on ſhort petioles, ovate, five-nerved, even, ſerrate, ciliate, netted, very brittle. Raceme terminating, brachiate; racemelets trifid, floriferous from the baſe. Flowers directed one way, upright. Anthers in the bottom of the umbilicus, ten. Fruits larger, globular, like pear, ſmooth, with an excavated umbilicus—ſmaller, with the umbilicus cloſed by five ſcales.

Found at Surinam by Dalberg[f]. Probably alſo native of Mexico and Braſil, if it be Texanari of Hernandez, and Coa-ghiyryo of Margraaf, and Piſo, as Vahl ſuppoſes from conſulting Margraaf's ſpecimen.

6. In Herman's ſpecimen, the leaves of M. malabathrica are narrower, more ſmooth, three-nerved. Calyxes leſs hiſpid, collected into racemes, not terminating the ſtem, as in that[g]. Calyx cylindric-urceolate, obſoletely grooved, ſmooth. Capſule ovate, ſlightly narrowing upwards, five-celled, opening by five cleſts at top, the edges of the cleſts bent back, inſomuch that a careleſs obſerver might ſuppoſe there were ten apertures. Seeds very ſmall[h].—Native of the Eaſt Indies.

7. Stem ſhrubby, rough-haired, with membranaceous corners. Leaves cordate at the baſe, acuminate, whitiſh underneath, nine-nerved with three nerves thicker. Racemes oppoſite, ſubdivided, with a ſeſſile flower in the forkings; the laſt pedicels three-flowered. Corollas rather large. Calyx oblong, five-cleft: ſegments lanceolate, acute. Petals five, obovate roundiſh, blunt, ſpreading, longer than the ſegments of the calyx, violet-purple. Filaments ten, the length of the corolla, filiform, purple. Anthers very long, ſickle-ſhaped. Germ oblong. Style long, curved. Stigma thickiſh. Fruit a berry[i].

Swartz affirms that the plant thus deſcribed is the ſame with M. holoſericea in the Linnean herbarium. Vahl informs us that Linneus confounded two different ſpecies under this name; the firſt deſcribed by him from the ſpecimen in Clifford's herbarium, the ſecond received many years later, which from ſome reſemblance he took to be the ſame. The plant deſcribed by Vahl is the ſame with that which is deſcribed by Linneus in the Species Plantarum, and different from that which is deſcribed above from Swartz, and is in the Linnean herbarium.—Native of Jamaica and Braſil.

8. This is a ſhrub with the ſtem rugged from ſtrigæ preſſed cloſe to it. Leaves ſubpetioled, ſtrigoſe above, the nerves only ſtrigoſe underneath. Pedunckes oppoſite or terminating, one-flowered, drooping, generally two-leaved. Calyx very ſtrigoſe. Corolla purple.—Found in New Granada by Mutis[k].

9. Native of Jamaica.

10. This is a tree with rugged branches. Leaves petioled, broad-lanceolate, rugged above with whitiſh briſtles, beneath chiefly on the nerves, ſcarcely ſerrate on the edge except by ſtiffiſh briſtles as on the upper ſurface; five diſtinct nerves run from the baſe to the top, the outermoſt of which is near the edge. Calyxes at the tops of the branches, hiſpid with whitiſh briſtles[l]. Capſule cloathed with the urceolate calyx, rugged with rigid briſtles preſſed cloſe, ovate, five-celled, opening at top by five cleſts: cells ſtuffed with a ſoft dark blood-red pulp. Seeds numerous, ſmall, kidney form-globular, of a dun colour[m].—Native of the Eaſt Indies.

11. This is an upright ſhrub, the height of a man. Stem ſmooth and even. Branches upright, from round angular, ſmooth and even. Leaves petioled, oppoſite and decuſſated, lanceolate-ovate, ſmooth on both ſides, very thin, ſometimes wrinkled a little underneath, ſomewhat ſhining, deep green. Racemes terminating, compound, erect, panicled: branches oppoſite, decuſſated; branchlets alſo oppoſite: flowers cluſtered, on ſhort pedicels, white, ſmall. Calyx ſuperior, five-toothed: teeth blunt, ſhort. Petals five, inſerted below the teeth, ſubſeſſile, roundiſh, entire. Filaments ten, fixed to the calyx below the petals, longer than the corolla, knee-jointed. Anthers erect, perforated at the top. Germ roundiſh. Style erect, longer than the ſtamens. Stigma thickiſh, truncate, concave. Berry roundiſh, at firſt white, then blue and at length black, five-celled, with a very dark blue juice[n]. According to Gærtner, the fruit is globular, grooved, the ſize of the common red Currant. Seeds large in proportion to the ſize of the fruit, angular, lucid, yellowiſh with a broad dark ſpot at the umbilicus. Embryo ſubcylindric, ſubſpiral, making a turn and half.—Native of Jamaica.

12. This tree is about fifteen feet high, with ſubreclining, aſh-coloured branches, the younger ones tomentoſe. Leaves ſometimes very ſlightly crenate at the edge, green and ſmooth above, tomentoſe and yellowiſh underneath, petioled, the inner nerves uniting before they arrive at the baſe. Racemes branched, tomentoſe, terminating, in pairs. Flowers ſmall, void of ſcent, yellow. Calyx four-toothed. Petals four,

[a] Juſſieu. [b] Obſ. [c] Linn. ſpec. [d] Swartz obſ.

[a] Gærtner. [b] Swartz. [c] Linn. ſuppl.
[d] Linn. zeyl. [e] Gærtner. [f] Swartz.

twice as long as the calyx. Germ roundiſh, tomentoſe, ſubinferior. Style longer than the ſtamens. Berry ſubglobular, four-celled. Seeds very ſmall, neſtling. Juice of the berry purple *.—Native of the Weſt Indies, flowering in march.

13. Native of the Eaſt Indies.

14. This is a tree with ſtiffiſh, round, hiſpid branches. Leaves cordate, ovate, ſtiffiſh with hairs, very thick and tomentoſe. Flowers at the ends of the branches, ſubſeſſile. Calyx ſtout, ſtrigoſe with hairs. Corolla a little hairy on the outſide.—Found in New Granada by Mutis †.

15. This ſhrub, when alone, grows erect, and throws out long branches, which lie on the next trees or ſhrubs; when it is next to a tree, it ſhoots right up, and fixes itſelf into the bark by fibres, at the ſame time throwing out its long lateral branches.—Native of Amboina ‡.

16 to 50. We have here a prodigious harveſt of new ſpecies found by Swartz in the Weſt Indies. N. 24. in Jamaica, Hiſpaniola, &c. N. 25, 27, 29, 32, 34, 40, 43, 46, 49, 50, are natives of the Weſt Indies in general. N. 30. of Hiſpaniola. N. 31. of Montſerrat. N. 47. of St. Chriſtophers: and all the reſt of Jamaica. I have to lament that the deſcriptions are not yet publiſhed, or at leaſt not arrived in England.

Aublet has twenty-one ſpecies under the name of Melaſtoma, beſides others under different names. Some of theſe are the ſame with thoſe of Swartz.

24. M. praſina is M. lævigata of Aublet, who thus deſcribes it. Trunk four inches in diameter, and five or ſix feet high, with a whitiſh, ſolid, compact wood. Branches and twigs from the top, long, four-cornered. Leaves pale green, ſlightly toothed at the edge, ending in a point, five-nerved; nerves red. Flowers very ſmall. Petals five, white. Filaments ten. Berry blue, ſmall, not very ſucculent, four or five-celled.—Native of the Weſt Indian iſlands and Guiana.

25. Trunk as thick as the human thigh, with a ruſſet-coloured bark almoſt ſmooth, very ſtraight, and twenty feet high. Branches and twigs oppoſite, ſquare. Leaves ſeſſile, a foot and half long, and half as broad in the middle, very green above, white beneath and ſmooth, having five large ribs. Flowers white §.

27. This is a middle-ſized tree, with a trunk four or five feet high, and four or five inches in diameter, covered with a gray bark. Wood white and briſtle. Branches long, ſubdivided, red, having four blunt corners. Leaves decuſſated, yelloviſh green above, ſlightly downy and tawny underneath: the largeſt are ſix or ſeven inches long, and three wide. Petiole an inch long, channelled above, convex beneath. Calyx five-toothed, red, with two ſmall leaves or ſcales at the baſe. Petals five, white, with a yellow or red claw. Filaments ten, yellow. Anthers two-celled, each of which opens by two valves, and at the baſe on the outſide is a gland. Berry not very ſucculent, three-celled.—Native of Cayenne and Guiana ‖.

28. Melaſtoma holoſericea of Vahl may probably be the ſame with M. albicans of Swartz.

50. Height about three feet. Stem four-cornered, with ruſſet hairs, throwing out very ſlender branches from the top. Leaves decuſſated, with a very ſhort ruſſet down above, ſmooth underneath, with five and ſometimes ſeven nerves. Petiole ſhort, villoſe, channelled above and convex beneath. Calyx divided into five ſharp lobes. Petals five, white. Filaments ten, on a red diſc, red. Anthers two-celled. Capſule five-celled, and opening at top by five valves.—Native of Cayenne ¶.

51. Native of the Society Iſles. Found in may 1774.

52. Branches herbaceous, four-cornered, rough-haired, as is the whole plant. Leaves two inches long, a little attenuated, five-nerved beſides thoſe on the edge, very ſeldom ſeven-nerved, ſoft on both ſides with abundance of diſtinct hairs. Petioles an inch long. Pedunceles axillary, oppoſite, longer than the leaf, once or twice biſid at top. Pedicels one-flowered; a flower in the forking ſhortly peduncled. A petioled leaf on each ſide at the diviſions of the peduncle, of the ſame ſtructure with the ſtem-leaves, but ſmaller. Flowering calyx oblong, with five linear-ſubulate ſegments, longer than the calyx itſelf, ſmooth within. Petals five with ſhort claws. Filaments ten, five at the bottom of the calyx, on one ſide longer, ſtronger, antheriferous, the length of the corolla, one knee-jointed longer than the reſt: five more ſlender, inſerted into the claws of the petals, ſhorter, without any anthers. Anthers ſtout, attenuated into an awl-ſhaped beak thickened at top. Style the length of the ſtamens. Capſule globular, ſmooth, the ſize of a pea, with a ſlender groove and two raiſed lines.—Cayenne, von Rohr **, and Aublet.

53. Branches four-cornered, ſmooth. Leaves oppoſite, from four to ſix inches long, ſpreading very much, ſharp at both ends, obſcurely toothed outwards, ſmooth on both ſides, having three beſides the marginal nerves. Petioles two inches long, ſubtriquetrous. Panicle terminating, erect, a palm in length: branches ſpreading, the loweſt four, the reſt oppoſite, ſmooth, trichotomous, jointed, as is alſo the common peduncle: joints a little widened at the top; branchlets divaricated, three-flowered. Flowers pedicelled, calyptred: calyptre conical, acute, tranſverſely deciduous. Calyx the ſize of Coriander ſeed, truncate, even, very ſmooth, greeniſh aſh-colour. Petals five, oblong, yellow. Stamens twelve or thirteen, the length of the corolla. Anthers linear, blunt at both ends, yellow on the back, pale at the edge, ſubemarginate at the baſe.—Found at Montſerrat by Ryan.

54. Branches roundiſh at bottom, obſcurely four-cornered at top, covered with ſtrigæ preſſed cloſe and ſubſerruginous, rugged: branchlets floriferous, oppoſite, four-cornered, ſtrigoſe. Leaves oppoſite, an inch long or a little more, acute, three-nerved, ſubtriplicate; the younger ones hairy on both ſides, thoſe which are more advanced ſhining above, very finely ſtriated, ſmooth except in the middle between the nerves and towards the edge; paler underneath, more rugged and hairy; hairs on the younger leaves broad at the baſe, ending in a briſtle, vaniſhing with age. Petiole very ſhort, channelled above, convex beneath, ſtrigoſe. Peduncles from the upper axils, ſolitary, oppoſite, at the ends of the branchlets and branches in threes; the lateral one-flowered, the middle three-flowered, the flowers on ſhort pedicels. Braſtes fix, imbricate, ovate, mucronate, ſhorter than the calyx, covered with ſtrigæ. Calyx oblong, covered with cloſe-preſſed ſtrigæ, broader and longer than in the reſt of the plant; ſegments five, awl-ſhaped, erect, ſmooth within. Petals five, one larger than the reſt, wide, rounded, purple. Stamens ten, below the inſertion of the petals.—Found in Guiana by von Rohr and Aublet.

55. Branches round, purpliſh, as are alſo the petioles, peduncles and calyxes rendered hiſpid by ruſeſcent hairs. Leaves oppoſite, two inches long, ſubhiſpid with yelloviſh hairs, eſpecially about the edge, cut out at the baſe into a ſmall ſinus, with a ſhort blunt point, having three nerves beſides the marginal ones, meeting below the point, paler underneath. Petiole ſhort, channelled above, keeled underneath. Racemes commonly ſolitary, but ſometimes in pairs, ſcarcely longer than the petiole, five-flowered: pedicels oppoſite, ſpreading very much, one-flowered. Calyx oblong: ſegments five, briſtle-ſhaped. Petals oblong. Stamens ten, the length of the corolla. Anthers linear, acute, bluntiſh at the baſe. Berry the ſize of black Pepper.—Native of South America.

56. Branches obſcurely four-cornered, ſmooth, above between the petioles hairy, even, purpliſh. Leaves oppoſite, remote, decuſſated, from two to three inches in length, and ſometimes a little longer, a little acuminate, three-nerved beſides thoſe at the edge; above even, veinleſs, purpliſh at the edge, beneath ſmooth, except that ruſeſcent hairs are ſcattered over the nerves, between the nerves very finely remotely and ſimply veined, veins commonly quite ſmooth, and purpliſh

* Jacquin. † Linn. ſuppl. ‡ Rumphius. § Sloane. ‖ Aublet. ¶ Idem. ** Vahl ſymb.

as are the nerves. Petioles very short, purplish, channelled above, roughish about the edge, but especially towards the tip. Racemes terminating with a branchlet growing out beyond, solitary, brachiate, four inches long. Common peduncles compressed-four-cornered, subvillose at top; partial opposite, very short, two-parted: a minute bracte under the ramifications and each flower. Flowers clustered, smooth, on the upper side of the branchlet. Calyx obsolete ly five-lobed, the size of Mustard seed. Petals five, wedge-form. Stamens ten, the length of the corolla. Anthers curved inwards, bright purple at the sides, whitish within and at the tip, brown on the back, a little longer than the petals. Style the length of the stamens.

Vahl regards the species figured by Aublet t. 156. as the same with this, but it is probably different. He also doubts whether M. ciliata, act. soc. hist. nat. par. 1. 109. be different from this.—Found in Cayenne by von Rohr.

57. Branches round, dichotomous, with a brown bark, those with the petioles, both sides of the leaves, peduncles and calyxes hispid with long distinct bristles; those on the branches thicker at the base, rufescent, spreading very much; those on the leaves and other parts pale yellow. Leaves two or three inches long, acuminate, bluntish; the teeth emarginate with a bristle, alternately a little larger, having five nerves besides those at the edge, the inner ones meeting below the point, simply veined between them. Petioles an inch long, grooved above. Peduncles at the forkings and end of the branches, solitary, sometimes in pairs, an inch and half long; pedicels opposite, commonly four, a little thicker towards the flower, spreading very much, short; the lowest often three-flowered, with the middle flower sessile. The five segments of the calyx bristle-shaped; when in fruit it is subovate. Petals five, oblong, short. Stamens ten, the length of the petals. Anthers pale at the edge, waved, awl-shaped, curved in at the base, a little longer than the filaments. Berries a little smaller than black Pepper.—Found by von Rohr and Aublet in Cayenne.

58. Branches purplish, alternately compressed towards the top, the angles hispid with long spreading purple bristles, the sides smooth and even. Leaves remote, a foot long, five-nerved, the tender ones three-nerved, transversely veined, somewhat netted, marked with lines above along the veins, and having a few yellow hairs scattered between them; they are pale green underneath, with the nerves and veins standing out and purple, the larger ones are pubescent. Petioles two inches long, flat, striated, hispid at the edge, terminated at top by an obovate bladder, an inch long, with some bristles scattered about it. Raceme terminating, upright, a palm or somewhat more in length, subcompounded. Common peduncle alternately compressed, somewhat angular by means of a raised decurrent line, purple, seldom hispid; to the partial peduncles a little wider. Partial peduncles opposite, short; the lowest trifid, the lateral pedicels one-flowered, the middle one three-flowered; the rest three-flowered, with the middle flower sessile. Calyx turbinate, purple, very short, five-toothed, having a few long hairs scattered about the sides and edge. Petals five, roundish. Stamens ten, the length of the corolla. Anthers short, a little longer than the filaments, awl-shaped, purple on the back and at the top, pale about the edge. Style the length of the stamens. Stigma flattened out, orbiculate, a little convex above. Found in Cayenne by von Rohr, in Cayenne and Guiana by Aublet, who fond of multiplying genera, makes this a distinct genus by the country name of Tococa.

59. The branches seem to be scandent; they are acutely four-cornered, compressed at top, with strigose ruggedish angles. Leaves two or three inches long, attenuated, acute, obtuse at the base, five-nerved, having close-pressed hairs scattered over the upper surface, with a small impression to each hair, by no means rugged, greenish yellow underneath, smooth except on the nerves and at the edges, where they are hairy. Petioles short, flat, hairy. Peduncle terminating, erect, an inch long or more. Flowers five or six, collected into a head, sessile. Involucre four-leaved; the two outer leaflets lanceolate, an inch and half long; the two inner ovate, shorter by half; all coloured at the base, the rest very like the leaves, generally five-nerved. Bracte at the base of each flower, membranaceous, lanceolate, almost the length of the calyx, hairy at the back. Calyx smooth, tubular, surrounded at the base by long gray hairs, submembranaceous, nerved, short, five-cleft; segments lanceolate, attenuated, subciliate. Petals five, oblong, shorter by half than the calyx. Stamens ten, longer than the corolla: at the top of the filaments are two little bodies, which are oblong, subpedicelled, yellow, blunt, appendiceled: anthers the length of the filaments, linear, acute, yellow, brown at the back, straight. Germ oblong, crowned by many bristles. Style filiform, the length of the stamens.—Native of the West Indies, where it was found by Schumacher, a Danish surgeon.

60. Branches obtusely quadrangular, covered at top, as are also the petioles and calyxes, with frequent close-pressed bristles. Leaves three inches long and more, attenuated to both ends, acute, three-nerved, besides those along the edge, with yellowish close-pressed bristles along the nerves and veins, those on the branches a little narrower, scarcely rugged, pale green underneath. Petioles short, roundish. Flowers commonly three at each axil, on very short peduncles. Calyx turbinate, obscurely four-toothed. Petals four, ovate. Stamens eight, shorter than the corolla. Anthers short, linear-oblong, blunt, purple, dusky purple on the back.—Native of the Caribbee islands [1].

It differs from M. fasciculata of Swartz, in having broader leaves, rugged above, with soft hairs underneath; flowers infrafoliaceous on longer peduncles several; calyxes smaller, smooth.

61. Branches roundish at bottom, four-cornered towards the top, hoary with meal, dilated below the leaves. Leaves from three to five inches in length, those next the corymb lanceolate, below quite entire; the upper surface very smooth and even, hoary underneath except the marginal nerves springing from the base, veins simple remote, the nerves of the more advanced leaves yellowish; the younger leaves mealy. Petioles and peduncles mealy, flat above, keeled underneath. Corymbs terminating, trichotomous, fastigiate. Universal peduncles in threes, compressed, as are also the partial ones, jointed, with the joints wider at top. Calyx yellowish green, somewhat mealy, globular at the base, contracted above: border somewhat flattened out, obscurely four-lobed. Petals four, oblong, yellow. Stamens eight, a little longer than the corolla. Anthers linear, yellow at the back, whitish at the edge.—Found in Montserrat by Ryan.

62. Branches softly and closely villose, four-cornered, jointed; joints three inches long, gradually shorter upwards, channelled alternately on the opposite sides, by a narrow membranaceous edge standing out. Leaves four or five inches long, triple-nerved besides those on the edge which spring a little above the base, very finely toothletted, ciliate, villose on both sides, especially underneath on the midrib and nerves, rugged above with raised dots, underneath not dotted, less rugged, paler. Petioles closely villose, short, roundish. Peduncles from the alternate axils, solitary, two inches long. Flowers six in each whorl, remote, the lower pedicelled, the upper sessile. Pedicels one-flowered, sometimes two-flowered; the lowest longer, unequal. Calyx four-cleft, villose; segments linear-lanceolate, short, reflex. Petals four, lanceolate, small. Stamens eight, a little longer than the petals. Berry globular, three times the size of Mustard seed.—Native of the Caribbee islands [1].

63. Stem from two to three feet high. Branches round below, four-cornered above, dichotomous, smooth, purplish. Leaves above on the branches, from two to three inches long, oblong, attenuated at the base, subcoriaceous, a little reflex at the edge, the serratures very minute, remote, ending in a short bristle, pressed close to the margin of the leaf, which is triple-nerved,

[1] Forsyth. [1] Idem.

smooth

ſmooth on both ſides, pale underneath, ſomewhat rugged. Petiole an inch long, ſomewhat channelled above, convex underneath. Pedunceles ſix or ſeven, ſhort. Flowers ſmall. Calyx truncated, ſubſtrigoſe when examined with a glaſs. Petals four, ſmall, ovate, attenuated. Stamens eight, the length of the petals. Anthers cuſous, paler at the edge, oblong, blunt at both ends, the length of the filaments. Style longer than the ſtamens. Stigmas blunt, ſubcapitate. Berry the ſize of Coriander ſeed, globular, when examined with a glaſs appearing to have ſtrigoſe cloſe-preſſed hairs thinly ſcattered over it.—Found in the iſland of Montſerrat, towards the tops of the mountains, by Ryan.

64. Branches obſcurely quadrangular, trifid, ſmooth below, above ſubhiſpid with gray ſcattered curled hairs, as are alſo the petioles and pedunculs. Leaves three inches long, ſmooth on both ſides, even, having frequently minute white dots ſcattered over the upper ſurface, eſpecially the younger ones, underneath pale green, netted-veined, nerves and veins yellowiſh: the younger ones marked with lines above along the tranſverſe nerves. Petioles ciliate, ſmoother and thicker towards the baſe. Thyrſe brachiate, a palm in length. Partial pedunculs oppoſite, as are the common pedunculs at the ramifications knotty, the younger ones dirty gray with ſhort hairs, once, twice, ſeldom thrice trichotomous, the laſt branch three-flowered. Pedicels ſhort. A lanceolate leaf on each ſide beneath the loweſt ramifications of the thyrſe. Bractes briſtle-ſhaped. Calyx commonly four-lobed, dotted with white, ſmooth: lobes rounded. Petals four, oblong, ſmooth. Stamens eight. Style longer than the corolla.

Ryan, who diſcovered it in Montſerrat, obſerves that it is a very beautiful ſhrub, from four to ſix feet high, with a regular head like an Orange tree. The large ſcarlet flowers, in thyrſes, cover the whole head. The leaves are wrinkled; and the flowers are ſometimes white.

65. Branches obtuſely quadrangular, tomentoſe with cloſe curled ferruginous hairs, gray-rufeſcent at top. Leaves on very ſhort petioles, from two to three inches long, bluntiſh at both ends, very finely toothletted, above ſomewhat wrinkled and rugged, underneath ſoft, yellowiſh gray, with five nerves beſides thoſe on the edge; the younger leaves are gray-tomentoſe on both ſides. Flowers three or four on each ſide, ſmall. Calycine ſegments four, ovate, ſmall, villoſe on the outſide. Petals four, oblong. Stamens eight, the length of the corolla. Anthers linear-oblong, purple, almoſt the length of the filaments. Berry globular, the ſize of Coriander ſeed.—Found by von Rohr in the Weſt Indies *.

66. Stem ſhrubby, ſix feet high, upright, round, hiſpid, with ſpreading branches. Leaves hairy on both ſides, rugged, petioled. Flowers large, red-purple, on many-flowered, upright, terminating pedunckes. Calyx five-cleft. Petals five, rounded, ſpreading. Filaments ten, brown, bent back, with a long tail hanging down. Berry calycine, ovate, hiſpid, juiceleſs, five-celled. Seeds many, ovate, very ſmall, without any pulp.—Common in Cochinchina.

Fragarius niger of Rumphius, which Linnæus aſſigns to his malabathrica, ſcarcely differs from this except in the number of nerves. M. grandiflora of Aublet (n. 52.) which is ſeven-nerved, is very nearly allied to this, but differs in having the baſe of the leaves cordate, and the ſtamens unequal.

67. This is a ſmall ſhrub, about ten inches high, upright, even. Leaves ovate. Flowers roſe-colored, on few-flowered, terminating pedunckes. Stamens twelve, ſix of which are bent back and have tails; the ſix other interior ones are upright, awnleſs, all fertile. Berry roundiſh, crowned with the ſegments of the calyx, five-celled, many ſeeded.—Native of China about Canton, and Cochinchina.

It differs from M. levigata and diſcolor more in ſtamens than leaves *.

Gærtner remarks, that the fruit in this genus being ſo various, ſome ſpecies bearing genuine berries, others capſules differing in ſituation and number of cells, the eſſence of it, ſo far as concerns the fruit, conſiſts in the ſeeds being void of any albumen, and lying in a ſoft pulp without any proper receptacle, and having a curved embryo.

We are cautioned by Ryan, to whoſe diligence we owe many of the ſpecies from the Weſt Indies, not to attend too much to the ſmoothneſs or hairineſs of the leaves in this genus, that of Pſychotria, and other inhabitants of mountains; becauſe they vary much in this reſpect, according as they grow in a rich ſoil and peaceful valley, or on a rugged brow expoſed to winds and weather.]

Mr. Miller has eighteen ſpecies, natives of the warm parts of America, where he ſays there are many more ſpecies. Moſt of thoſe which he has mentioned were found by Dr. Houſtoun in Jamaica, whence he ſent many of the ſeeds to Europe, ſome of which ſucceeded; but moſt, if not all the plants which were raiſed from them were loſt in the ſevere winter of 1740, ſince which time they have not been recovered in Europe. There is great beauty in the diverſity of leaves in theſe plants; many of them are very large, and moſt of them are of different colours on the two ſurfaces, their under ſide being white, gold colour, or ruſſet, and their upper of different ſhades of green. Their flowers have no great beauty, but for the ſingularity of the leaves, they deſerve a place in all curious collections.

[Mr. Miller's ſpecies are ſo confuſed, that it would be difficult to aſcertain any of them, if many of his ſpecimens did not yet exiſt in the Bankſian herbarium.

1. Melaſtoma Plantaginis folio, as he calls it. His references are the ſame with thoſe which Linnæus puts to his M. Acinodendron, which is very different from this. Miller thus deſcribes it.] It riſes four or five feet high, the ſtem and branches being covered with long ruſſet hairs. Leaves five inches long and two broad, covered alſo with the ſame ruſſet down, having five ribs running from end to end, but the three inner join before they reach the baſe, with ſmall tranſverſe ribs. The fruit is produced at the end of the ſhoots, it is a pulpy blue berry, as large as a nutmeg.

5. [M. groſſulariioides of Miller ſeems to be the ſame with M. levigata of Linnæus, our eleventh ſpecies.] It ſeldom grows more than ſeven or eight feet high, ſpreading out into many ſlender branches, covered with a ſmooth purple bark. Leaves lanceolate, five inches long, and two broad in the middle, ſmooth on both ſides, entire, acute pointed. The flowers are produced in pretty long hanging bunches, of an herbaceous colour, with ſtyles ſtretched out a good length beyond the petals, and permanent. Fruit ſmall, black when ripe.

6. M. bicolor, riſes four or five feet high, dividing into many ſlender branches, which are ſmooth. Leaves lanceolate, three inches long and one inch and a quarter broad, of a lucid green on the upper ſide, but white on the under, having three ribs which join before they reach the baſe, they are entire and placed alternately on the branches. The flowers are produced in a looſe panicle at the end of the branches; they are ſmall, white, and have pretty long tubes. Fruit ſmall, purple.

7. M. malabathrica [very different from the plant of the ſame name in Linnæus. Thus deſcribed by Miller.] Stem angular, ſix or ſeven feet high, ſending out branches oppoſite. Leaves lanceolate, oval, rough, hairy, dark green on the upper ſide, but pale green on the under. The flowers are produced at the end of the branches, two or three ſtanding together; they are large, and of a roſe colour, inclining to purple, ſitting in large hairy calyxes: theſe are ſucceeded by roundiſh purple fruit, crowned by the calyx, and filled with a purple pulp ſurrounding the ſeeds.

8. [M. levigata of Miller is the ſame with M. argentea of Swartz, our n. 25.

10. M. umbellata of Miller is the ſame with M. patens of Swartz, our n. 17.] Stem ſhrubby ten or twelve feet high, covered with a hairy bark, and dividing into many branches towards the top. Leaves heart-ſhaped ending in acute points; they are five inches

* Vahl Enum.

* Lourieo.

inches long and three broad towards the base, entire, dark green above and hoary underneath, with five longitudinal nerves, and many smaller transverse ones; they stand upon hairy footstalks, two inches and a half in length. The flowers are produced at the end of the branches in a sort of umbel; they are of a pale rose-colour, and pretty large, sitting on hairy calyxes, and succeeded by small black fruit, a little larger than Elder-berries.

[There are also specimens of his eleventh species M. racemosa, of his twelfth, M. verticillata, of his acuta, n. 13., of his glabra, n. 14., of his quinquenervia, n. 15., and of his octandria, n. 16.: but whether these correspond with any of the species already set down from Swartz or Vahl, or are distinct from them I cannot determine. Miller's octandria may perhaps be the same with fragilis of Linnæus's Supplement.]

PROPAGATION AND CULTURE.

The best way to obtain these plants is to have the entire fruits put up in dry sand as soon as they are ripe, and forwarded by the quickest conveyance. They should be taken out as soon as they arrive, and the seeds sown in pots of light earth, and plunged into a moderate hot-bed of tanner's bark. When the plants come up, and are fit to remove, plant each in a small pot of light earth, plunging them into the tan-bed. Afterwards treat them in the manner directed for ANNONA.

DESCRIPTIONS, &c.

1. This in warm countries grows to a large tree, spreading out into many branches. Leaflets notched and indented on their edges, deep green above, and paler underneath. The flowers come out from the side of the branches in long loose bunches. Petals blue. Fruit oblong, the size of a small Cherry, green at first, but when ripe changing to a pale yellow. Nut four or five-celled, with one oblong seed in each cell. It flowers in July, but does not often produce seeds. It drops the leaves in autumn, and puts out fresh ones in spring. The pulp surrounding the nut is poisonous, and mixed with grease, it is said will kill dogs. The nuts are bored and strung for beads by the Roman Catholics.

Native of Syria, and now common in Spain and Portugal. [Cultivated in 1656, by Mr. John Tradescant Jun.[a]]

2. This which has been generally regarded as a variety, is thought by Swartz to be a distinct species, differing from that in being smaller and often flowering for two years together, the leaflets which are bright green, are seldom more than seven, wrinkled a little, deeper and more unequally serrate and acuminate.

Native of the East Indies.] Mr. Miller says, that some plants have been introduced into the West Indies, where he is informed they continue flowering and fruiting most part of the year; that he has received the fruit by the name of Indian Lilac, from which he raised many plants, but found them to be the same with that from Syria.

3. This becomes a large tree in India. The stem is thick, the wood of a pale yellow, and the bark of a dark purple colour and very bitter. The branches extend wide on every side. The leaves are compofed of five or six pairs of oblong acute-pointed leaflets, terminated by an odd one: they are serrate, of a light green colour, and of a strong disagreeable odour; they stand upon pretty long footstalks, oppofite or alternate. The flowers are produced in long branching panicles from the side of the branches: they are small, white, and fit in small calyxes, cut into five acute segments. Fruit oval, the size of small Olives, green, turning yellow, and when ripe changing to purple: the pulp is oily, acrid and bitter: the nut is white and shaped like that of the former. [Gærtner describes the fruit as a berried drupe, of an elliptic-globular form, and black, with a soft pulp, and a bony white shell; it has five or six grooves, and five or six cells, a wide little cavern within the base, from which a narrow canal ascends towards the top of the shell, opening into the cells at the top by five or six little apertures. Umbilical chords very short, reaching from the axis to the apex of the seed through the apertures. Seeds solitary, oblong, attenuated to both ends, compressed wedge-form, a little wrinkled, very dark rust coloured. The number of grooves and cells varies. Commelin gives only four cells, Gærtner's specimen had six, but the natural number is five.

Cavanilles has another species from Lamarck's herbarium, native of the East Indies, whence it was brought by Sonnerat.]

PROPAGATION AND CULTURE.

1. This sort is propagated by seeds (which may be obtained from Italy or Spain, where these trees annually produce ripe fruits in the gardens where they are planted:) the seeds or berries should be sown in pots filled with good light fresh earth, and plunged into a moderate hot-bed of tanners bark, where, if the seeds are fresh, they will come up in about a month or five weeks time. When the plants are come up they should be frequently watered, and should have a large share of free air, by raising the glasses every day; in June they should be exposed to the open air, in a well sheltered situation, that they may be hardened before winter. In october the pots should be removed under a

[a] Hort. kew.

hot-bed frame, where they may enjoy free open air when the weather is mild, and be covered in hard froſt. During the winter ſeaſon they muſt be refreſhed gently with water, but by no means repeat this too often, nor give them too much at a time; for their leaves being off, they will not be in a condition to throw off a ſuperfluity of moiſture.

In march following, you may ſhake out the plants from the ſeed-pots and divide them, planting each into a ſeparate ſmall pot, filled with light freſh earth, plunging them into a moderate hot-bed, which will greatly promote their rooting, and increaſe their growth, but they muſt not be drawn too much; and in june you ſhould remove them out into the open air as before, and during the three or four winters, while the plants are young, you muſt ſhelter them, to ſecure them from the cold; but when the plants are grown pretty large and woody, they will endure to be planted in the open air againſt a ſouth wall. The beſt ſeaſon for this is in april, at which time you ſhould ſhake them out of the pots, being careful not to break the earth from the roots, but only pare off with a knife the outſide of the ball of earth; then open your holes and put in the plants, cloſing the earth to their roots, obſerving if the weather is dry, to give them ſome water, which ſhould be repeated twice a week until the plants have taken root; but you muſt obſerve to plant them on a dry ſoil, otherwiſe they will be liable to miſcarry in ſevere froſty weather.

3. This ſort is now very rare in England, and alſo in the Dutch gardens, where ſome years paſt it was more common; it is propagated by ſeeds in the ſame way as the other ſort, but being much tenderer, the plants ſhould be kept conſtantly in the tan-bed while young. In the ſummer they may be placed under a frame, but in winter they muſt be removed into the bark-ſtove, and treated in the ſame way with other plants from the ſame countries. When the plants have obtained ſtrength, they may be treated more hardily, by placing them in winter in a dry ſtove, and in the middle of ſummer they may be placed abroad for two or three months in a warm ſheltered ſituation, but they ſhould not remain too long abroad; and during the winter ſeaſon they ſhould be ſparingly watered: with this management the plants will produce flowers annually, and as they retain their leaves all the year, they are ornamental in winter in the ſtove.

MELIANTHUS. (*From μελι and ανθος, honey-flower.*)
Lin. gen. n. 795. *Reich. n.* 859. *Schreb. n.* 1068. *Juſſ.* 297. *Tournef.* 245. *Herm. lugdb.* 415.
Claſs. 14. 2. Didynamia Angioſpermia.
Nat. order of *Corydales. Rutaceæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* large, five-parted, coloured, unequal: the two upper ſegments oblong, erect; the loweſt very ſhort, like a bag, gibbous downwards; the middle ſegments oppoſite interior, lanceolate, the uppermoſt ſimple, erect.

COR. *Petals* four, lanceolate-linear, with the tops reflex, from parallel ſpreading, turned outwards, forming the lower lip, as the calyx itſelf does the upper, connected at the ſides in the middle.

Nectary one-leafed, placed within the loweſt ſegment of the calyx, and faſtened to it with the receptacle, very ſhort, compreſſed at the ſides, gathed at the edge, turned downwards by the back.

STAM. *Filaments* four, awl-ſhaped, upright, the length of the calyx; the two lower ſhorter, united at the baſe. *Anthers* coalate-oblong, four-celled in front.

PIST. *Germ* four-cornered, gibbous, four-toothed. *Style* upright, awl-ſhaped, of the ſame length and in the ſame ſituation with the ſtamens. *Stigma* four-cleft, with the upper ſegment larger.

PER. *Capſule* quadrangular, half-four-cleft; angles ſharp, diſtant; cells inflated; partitions open in the centre for a receptacle of the ſeeds, gaping between the angles.

SEEDS in fours, ſubglobular, annexed to the centre of the capſule.

ESSENTIAL CHARACTER.

Cal. four-leaved, the lower leaf gibbous. *Pet.* four, with the nectary within the loweſt. *Capſ.* five-celled.

SPECIES.

1. Melianthus major. *Great Honey-flower.*
Lin. ſpec. 892. *ſyſt.* 581. *Reich.* 3. 204. *hort. diff.* 493. 1. *muſ.* 181. *Mill. illuſtr. Knipb. cent.* 12. *n.* 70.

M. africanus. *Herm. lugdb.* 414. *t.* 415.
Stipules ſolitary faſtened to the petiole.

2. Melianthus minor. *Small Honey-flower.*
Lin. ſpec. 892. *Reich.* 3. 202. *hort. diff.* 493. 2. *Vahl ſymb.* 3. 85. *Knipb. cent.* 8. *n.* 68. *Curt. magaz. t.* 301.
Stipules in pairs diſtinct-racemes axillary elongated, flowers in whorls, bractles linear elongated.

[3. Melianthus comoſus.
Vahl ſymb. 3. 86.

M. africanus minor ſoetidus. *Comm. rar.* 4. *t.* 4. *Raii dendr.* 120.
Stipules diſtinct, racemes infrafoliaceous, flowers alternate, bractles cordate, leaves villoſe above.

DESCRIPTIONS, *&c.*

Theſe are ſhrubby, with alternate unequally pinnate leaves on a winged petiole, with ſtipules either diſtinct or faſtened to the petiole. Flowers in ſpikes either axillary or terminating, each having a bractle. This genus is allied to Tropæolum in the cowl of the calyx, and in the ſituation of the petals and ſtamens, but it more reſembles Dictamnus in the habit, fruit and periſperm; it however differs very much from both *.]

1. Root woody, perennial, ſpreading. Stems many, woody, four or five feet high, herbaceous towards the top. Leaves large, embracing the ſtem at the baſe, where they have a large ſingle ſtipule faſtened on the upper ſide of the footſtalk, with two ears at the baſe, which alſo embrace the ſtem. The leaves have four or five pairs of very large leaflets, deeply jagged into acute ſegments; and between them runs a leafy jagged border or wing along the upper ſide of the midrib, ſo as to connect the leaflets at the baſe; they are of a gray colour. Spikes pretty long, ſpringing from between the leaves towards the top of the ſtalks. Corolla brown or chocolate colour.

[Linnæus remarks, that if this plant be ſhaken whilſt it is in flower, it diſtils a ſhower of nectar. He alſo informs us that it was ſent from the Cape of Good Hope to Thomas Bartholinus in Holland by Hermann, in the year 1672.—It was introduced into England in 1690, by Mr. Bentick *.]

2. This riſes with round, ſoft, woody ſtalks, five or ſix feet high, ſending out two or three branches from the ſide. Leaves not half ſo large as thoſe of the preceding, deep green on the upper, and whitiſh on the under ſide. The flowers come out from the ſide of the ſtalks in looſe hanging panicles, each ſuſtaining ſix or eight flowers, ſmaller than thoſe of the firſt ſort: the lower part of the petals is green, the upper ſaffron-coloured, and on the outſide, in the ſwelling part of the petals, is a bluſh of fine red.

[The leaflets are ſmooth above, houry underneath. Raceme a foot long, upright. Flowers remote, in whorls of four, pendulous. Bractles the length of the calyx. Segments of the calyx lanceolate, attenuated *.

Mr. Curtis remarks, that the ſtem, which is ſhrubby, and from three to five feet high, during the flowering ſeaſon is apt to exhibit a naked appearance, having then fewer leaves on it, and thoſe not of their full ſize; that the foliage has an unpleaſant ſmell; and that the nectar does not flow ſo copiouſly as in the large ſort, but is retained at the bottom of the corolla, and is of a dark brown colour.

Native of the Cape of Good Hope. Cultivated in 1708 by the Dutcheſs of Beaufort *.

3. Branches round, warted below, houry above. Leaves at the ends of the branches, approximating, alternate, five-paired. Leaflets oppoſite, ſeſſile, an inch and half long, lanceolate, deeply ſerrate; the ſerratures ſharper than in M. minor, acuminate, veinleſs, villoſe and greener on the upper ſurface, marked with lines along the nerves, houry underneath, ſoft. Petiole ſomewhat winged with the edge of the leaf running down it. Stipules awl-ſhaped. Racemes al-

* Juſſieu. * Hort. kew. * Vahl. * Hort. kew.

ternate, frequent, below the leaves on the branches, the uppermoſt ſometimes axillary, three inches long, nodding. Flowers approximating. Pedicels and peduncles villoſe-tomentoſe, a little thicker under the flower. Bractes villoſe, a little longer than the pedicel. Two ſegments of the calyx wide, ovate, acute, villoſe; the third linear, inferior. Capſule hoary.

Native of the Cape of Good Hope*.]

PROPAGATION AND CULTURE.

1. This plant was formerly preſerved in a green-houſe as a tender exotic, but if planted in a dry ſoil and a warm ſituation, it will endure the cold of our ordinary winters very well; and if in a ſevere froſt the tops ſhould be deſtroyed, yet the roots will abide, and put forth again the ſucceeding ſpring. The plants which grow in the open air always flower much better than thoſe in the green-houſe, being leſs drawn, which is always hurtful to the flowering of plants. The ſureſt method to have them flower in the open air is to cover the ſhoots in froſty weather with reeds or mats: and if they are planted againſt a ſouth wall and on dry rubbiſh, they may be faſtened up to the wall and covered, and not ſhooting ſo vigorouſly as in rich ground, they will be leſs ſucculent, and therefore not ſo liable to ſuffer by cold.

This plant may be propagated by taking off its ſuckers or ſide ſhoots, any time from march to ſeptember, obſerving to chuſe ſuch as are furniſhed with fibres, and after they are planted and taken root, they will require no farther care but to keep them clear from weeds: they may be alſo propagated by planting cuttings, during any of the ſummer months, which, if watered and ſhaded, will take root very well, and may afterwards be tranſplanted where they are deſigned to remain.

2. This not ſpreading like the firſt, is not propagated ſo eaſily, but cuttings planted upon an old hot-bed, the heat of which is over, and covered cloſe with bell or hand-glaſſes to exclude the air, will take root pretty freely; theſe may be planted in pots and ſheltered in the winter under a common frame for a year or two till they have obtained ſtrength, then they may be planted in a warm border, and treated in the ſame way as the former ſort, with which management I have ſeen them flower much better than any of thoſe which have been treated more tenderly, and theſe plants have perfected their ſeeds in good ſeaſons.

MELICA.

Lin. gen. n. 82. *Reich. n.* 88. *Schreb. n.* 113. *Gærtn. t.* 80. *Juſſ.* 31.

Claſſ. 3. 2. Triandria Digynia.

Nat. order of *Gramina, Graminæ* or *Graſſes.*

GENERIC CHARACTER.

CAL. *Glume* two-flowered, two-valved: *valves* ovate, concave, nearly equal.

COR. two-valved: *valves* ovate, awnleſs; one concave, the other flat and ſmaller. A *corpuſcule* between the florets, turbinate, pedicelled.

Nectary one-leafed, horizontal, ſurrounding the germ, fleſhy.

STAM. *Filaments* three, capillary, thickened at the baſe, connate, the length of the flower. *Anthers* oblong, forked at each end.

PIST. *Germ* obovate, turbinate. *Styles* two, briſtle-ſhaped, ſpreading, naked at the baſe. *Stigmas* oblong, feathered.

PER. none. *Corolla* incloſing and dropping the ſeed.

SEED ſingle, ovate, grooved on one ſide.

OBS. *The peduncled corpuſcule (which is the rudiment of a flower) gives the eſſential character: it conſiſts of two rudiments, or truncated alternate florets, with convoluted pellucid glumes.* Linn.—*Add, that the ſtamens are diloted at the baſe and connate, with a one-leafed nectary.* S.

ESSENTIAL CHARACTER.

Cal. two-valved, two-flowered: with the rudiment of one or two florets that are abortive, between the two others.

DESCRIPTIONS, *&c.*

1. Root perennial. Culms ſeveral, upright, from two to three feet high, round, ſmooth, with ſeven ſmooth, purple joints. Leaves lanceolate, mucronate, flat, from three to nine inches long, one or two lines wide, ſmooth underneath, ſlightly pubeſcent above, ſomewhat rugged downwards. A white nerve runs along the back. Ligule white, cloven. Sheaths ſtriated, the lower a little pubeſcent and rugged, the upper ones ſmooth. Panicle erect, cylindric, ſpiked, round, from two to three inches long, four lines wide, when young appearing to be ſmooth, but becoming feathered by age. Branches two or one ſpring from the ſcape, which are ſomewhat rigid, and divided from the very baſe into ſmaller and even very ſmall branches; the final peduncles, on which the flowers are placed either ſingly or in bundles, are very ſhort. Spikelets lanceolate, mucronate, ſtriated, two-flowered, green white and purple, ſhining, compreſſed a little, near three lines long, cloſed, ſcarcely one line wide. Larger glume of the calyx longer than the corolla, lanceolate, mucronate. Outer valve of the corolla, in the larger ſeſſile floret adorned with white feathers ſtanding out; but in the ſmaller pedicelled floret ſmooth; both are awnleſs. Anthers white. Stigmas white, feathered. The ſcape is entirely covered with the ſpikelets [b].

Native of the North of Europe. Introduced in 1771, by Monſ. Richard. It flowers in july [c].

2. Native of the Cape of Good Hope.

3. Is this different from Ehrharta calycina, Smith, ic. ined. 33. which is alſo a native of the Cape? In the Supplement of the younger Linnæus it is named Aira capenſis.

4, 5. Both natives of the Cape of Good Hope [d].

6. Root perennial, ſomewhat creeping. Culms a foot or a foot and half high, ſimple, upright, rugged, ſtriated, ſomewhat angular, below purpliſh. Leaves at the baſe of the culm ſhort ſcale-like, browniſh, as they aſcend becoming longer and narrower, a line and half broad, and ſlightly rugged. Ligule none. Panicle two or three inches long, bending down a little, with the flowers inclining one way, ſimple or branched; peduncles capillary, preſſed a little to the rachis, flexuoſe, upright, villoſe when magnified, eſpecially at the flower, where they are ſomewhat thickened. Spikelets uſually three-flowered; rudiment of the pedicelled floret forming a ſort of club. Calycine valves unequal, blunt, faintly ribbed, at firſt purple and finally of a browniſh hue. Outer valve of the corolla large, many-ribbed, moſt of the ribs ſcarcely reaching half its length; the inner one broad, flat and much ſhorter. Filaments quite diſtinct. Anthers yellow. Germ broad-ovate, pellucid. Styles naked below, above feathery and ſpreading. Nectary two little glumes, fleſhy and truncated [e]. Seed ovate-oblong, attenuated downwards, convex on one ſide, and having a longitudinal groove along the other; ſmooth, ſhining as if oiled, dark-bay and almoſt cheſtnut-coloured [f].

Native of many parts of Europe, particularly the northern countries, in rocky and ſhady ſituations: with us in Yorkſhire, Weſtmoreland and Cumberland; alſo in Scotland. It flowers in july and auguſt.

This plant, as Mr. Curtis obſerves, accords ſo ill with Gramen montanum ſpicatum of Cluſius, which is referred to it by Schreber, Haller and Scheuchzer, that he probably intended ſome other ſpecies.

7. Root perennial. Culm ſimple, a foot and half or more in height, where it is covered with the ſheaths of the leaves ſomewhat angular, rugged and ſtriated, at bottom of a dull purple colour. Stem-leaves about five, yellowiſh green, flat, a line and half or almoſt two lines broad, terminating gradually in a point, feeling rough when drawn backwards between the fingers, on the upper ſide ſomewhat hairy, the edges when magnified appearing finely ſerrate: ligule ſcarcely any, but what is very remarkable, a ſmall ovate leaf with a long point, upright and coloured, riſes from the fore part of the mouth of the ſheath. Flowers in a looſe panicle; the lowermoſt flower-ſtalks growing two together, the one ſhorter than the other, bearing three flowers, and even ſeven or eight when cultivated in a garden; the uppermoſt growing ſingly. Spikelets pedicelled, at firſt of a dark purple colour, beardleſs, each containing two flowers. Calycine valves coloured and ſhining; the outer ovate, concave, five-ribbed, ending in a ſhort point; the inner leſs, ovate-lanceolate, three-ribbed. Hermaphrodite flower ſeſſile, the outer valve large, bellying, with its edges embracing the inner, which is flattiſh, with membranaceous edges turned back, eſpecially near the baſe: ſterile flower pedicelled. Germ ſmooth, ſhining, yellowiſh: ſtyles ſeparate at bottom and ſpreading out: ſtigmas villoſe. Nectary a very minute entire ſcale, at the baſe of the germ. Seed ovate, rather large and blackiſh. The delicacy and ſtriking colour of the panicle, joined to its place of growth, in woods, readily diſtinguiſh this from all our other graſſes [g].

Native of Sweden, Germany, Switzerland, France and England. In moſt of the woods near London. Mungewell, Ardley and Stokenchurch woods in Oxfordſhire, &c.

There is a confuſion in ſome of the ſynonyms of theſe two ſpecies; thoſe of Bauhin and Moriſon are clearly wrong.

8, 9. Natives of the Cape of Good Hope [h].

10. Culms filiform, very narrow, half a foot high, very much branched, covered with the ſheaths of the leaves. Leaves very narrow, rolled inwards, ſpreading a little at the baſe. Racemes terminating, ſimple, capillary, few-flowered. Calyx ſhorter by half than the florets, which are oblong and awnleſs, with a truncated barren pedicelled floret between them.—Found in Italy, by Scopoli [i].

11. Root perennial, thick, whitiſh or browniſh, flexuoſe and villoſe. Culm from a foot to two feet in height, ſomewhat bulbous at the baſe, upright, having only one knot, and that near the baſe, above naked and ſmooth. Leaves for the moſt part three or four, about a hand's breadth in length, blueiſh-green, rather broad, acuminate, ſtiffiſh, the lower ones flat, the upper ones ſomewhat rolled up, hairy at the edges. Ligule none. Sheath ſhort, ſtriated. Flowers in a branched panicle, a hand's breadth or more in length; the branches cloſing together ſo as to form a kind of ſpike. Spikelets containing two, three or four flowers, but moſt commonly three, with the rudiment of a flower in moſt of them: the young ones flattened, the full-grown ones roundiſh, obtuſe, ſlightly diverging. Calycine valves pointed, keeled, with purple edges.

[a] Pollich. [b] Hort. kew. [c] Thunb. prodr. [d] Gærtner. [e] Curtis. [f] Linn. mant. [g] Curtis. [h] Thunberg. [i] Linn. mant.

Valves of the corolla nearly equal, the outer, which is rather larger, embracing the inner, three-ribbed, ſlightly pointed, the edges purple; the inner valve two-ribbed, paler, obtuſe, and a little ſhorter. Nectary, two very ſhort broad truncated emarginate ſcales. Anthers purple. Germ very minute, ſmooth and ſomewhat ovate: ſtyles branched to the bottom and purple.

Linnæus at different periods placed this graſs in different genera: in his Flora Lapponica it appears as a *Poa*; in his Species Plantarum and Flora Suecica as an *Aira*; in his Syſtema Vegetabilium as a *Melica*. If the ſpikelets be examined when the plant is young, they are very like thoſe of Poa, being pointed, flattened, and containing uſually from three to five flowers; as they advance, their form alters, they become rounder, and more like the flowers of Aira aquatica; ſo that if the rudiment were wanting, it might be difficult to determine in which genus it ſhould be placed, but that being preſent, we are under no difficulty in claſſing it with Melica.

This graſs is eaſily known by its having only one knot, and that near the baſe; and by the ſtamens and ſtigmas being of a deep purple colour. Merret's name of Gramen ſpica lavendulæ is very expreſſive of its appearance when in flower.

It is common on wet moors and heaths, flowering from July to the end of September. Being harſh and late, it does not ſeem adapted to agricultural purpoſes. It varies greatly in ſize [1].

The fiſhermen in the iſle of Skie make ropes for their nets of this graſs, which they find by experience will bear the water well without rotting [2].

12. This has the ſtature of the next ſucceeding ſpecies. Panicle rod-like, with ſlender peduncles longer than the flower, branched eſpecially below. Lower valve of the calyx obovate, blunt, very large, coloured; upper valve, only one-ſixth of the ſize, remote from the lower, ſcarioſe and coloured at the top. Flowers two, alternate, beſides the rudiment. Outer petal to each oblong, ſtriated with ſixteen nerves; the middle ones muricated; the ſide ones ciliate with many briſtles; but the apex of the petal is ſcarioſe with a thin even membrane, blunt and coloured. Inner petal ſimple. Rudiment oblong.

Native of Braſil, *Arduini* [3]. Jamaica, *Sloane*.

13. Leaves two lines and a half wide. Panicle often half a foot long, thick and branched, the branchlets preſſed cloſe to the culm. Spikelets three or four-flowered. Calycine valves obtuſely mucronate, the inner longer. Florets alternate, not very remote, ſmaller the higher they are; the outer glume embraces the other and the next floret above; inner valve ſhorter by half or a third, flat or concave outwards, blunt, membranaceous with a green edge. The extreme floret is pitcher-ſhaped, one-valved, permanent, containing the rudiment of a germ with a ſhort ſtyle; it is therefore a female or neuter floret.

Native of Siberia [4]. Introduced in 1770, by Monſ. Richard [5].

β. Is a native of Canada, and differs ſo much in habit that it is probably a diſtinct ſpecies [6].

14. Leaves on the culm two, alternate. Culm a foot and half in height, even, with two joints. Spike a finger's length, imbricate with lateral, lanceolate, acuminate, three-nerved leaflets, a little longer than the flowers, one to each. Flowers pubeſcent, with a white edge. Calycine leaflets flat; the inner ſhorter than the floret. Florets two to each calyx, a larger and a ſmaller, beſides the rudiment. Outer valve of the corolla obovate, white-ciliate, very blunt, emarginate; inner long, narrower, even, lanceolate.

Native of the Cape of Good Hope, where it was found by Sparrmann [7]. Thunberg, who alſo found it at the Cape, has with reaſon removed this ſpecies into the genus *Cynoſurus*; but not having been noticed in this work under that genus, it is inſerted here.

PROPAGATION AND CULTURE.

Theſe graſſes are eaſily propagated by the ſeed, or by parting the roots in autumn. None of them are cultivated for feeding cattle; though both *ciliata* and *nutans* are ſaid by ſome to be very agreeable to ſheep. M. nutans and uniflora being elegant graſſes deſerve a place in curious gardens, together with ſome of the Cape ſpecies.

DESCRIPTION, *&c.*

This is a tree with a middle-ſized unarmed trunk. Branches ſpreading. Leaves pinnate, with two pairs of leaflets. Common petiole elongated, almoſt round, but a little compreſſed between the leaflets, ſeldom winged. Leaflets ſubſeſſile or on very ſhort petioles, ovate, acuminate at both ends, entire, nerved, ſmooth on both ſides, bright green. Racemes compound, terminating; branchlets alternate, ſimple, upright, many-flowered. Male flowers more abundant, deciduous, more yellow: the hermaphrodites ſcarcely larger. Nectary and anthers yellow. Drupe twice as large as a nutmeg, with a thin and ſomewhat briſtle bark covering the nut, which has a ſweet acid gelatinous ſubſtance in it, like the yolk of an egg [8].—Gærtner deſcribes it as a ſuperior ovate berry, ſmooth or rugged with ſmall miliary granules, acuminate at top or at both ends, coriaceous thickiſh, one-celled, having a groove on one ſide.

Jacquin was informed at Curaçoa that there were male and female trees, but Swartz has aſcertained that one tree bears hermaphrodite flowers, another male flowers, and that the latter are moſt common. They flower in april, and the fruit is ripe about midſummer.

Native of South America, and cultivated in the Eaſt Indies. Browne ſays it was brought to Jamaica from Surinam; that it thrives well in the low lands about Kingſton, riſing ſometimes to the height of ſixteen or eighteen feet or more; that the fruit is very mellow and grows to the ſize of a large plum, and that it ſeldom brings more than one ſtone or ſeed to perfection. He calls it Genip tree, which is from the Dutch *Knippen*. The Spaniards call it *Monos*. According to Jacquin it is wild about Carthagena, and commonly cultivated at Curaçoa. It was introduced here in 1778, by Thomas Clark, M. D.

MELICOPE. (*So named by Forſter, from* μελι, *honey, and* κωπη *a ſection or inciſion: the nectary being very much cut.*)

Branches attenuated red like, leaves tomentoſe underneath, ſtem ſhrubby.

DESCRIPTIONS, *&c.*

1. Garden or common Baum has a perennial root, and an annual ſtalk, which is ſquare, branching, from two to three feet high. Leaves by pairs at each joint, two inches and a half long, and almoſt two inches broad at the baſe, growing narrower towards the top, indented about the edges; the lower ones upon pretty long foot-ſtalks. The flowers grow in looſe ſmall bunches from the axils in whorls, upon ſingle pedunculs. They are white, or yelloviſh, and appear in july.

[The leaves are hairy above, ſmooth beneath. The whorls are ſhorter than the leaves; the pedicels ſimple and unequal. Stipules ovate-lanceolate. Teeth of the calyx broader, awned. Corolla ſometimes tinged with red [a].

Baum or Balm is a native of the ſouthern parts of Europe, eſpecially in mountainous ſituations, in Switzerland, Carniola, Sileſia, the South of France, Italy. It was cultivated by Gerarde in 1596; and was probably much earlier in our gardens, having been ſo much celebrated among the Arabian phyſicians.

Baum in its recent ſtate has a weak roughiſh aromatic taſte, and a pleaſant ſmell, ſomewhat of the lemon kind, whence its name *Citrago* in Geſner. Anciently it was generally recommended in hypochondriacal affections, and by Paracelſus the *primum ens Meliſſæ* promiſed a complete renovation of man: even Hoffman and Boerhaave, probably biaſſed by the Arabian phyſicians, deemed it an efficacious remedy. It is now only uſed as tea, for a grateful diluent in fevers, either alone or acidulated with the juice of lemons. The eſſential oil probably poſſeſſes no qualities different from many other aromatics and cordials [b].

From the fondneſs of Bees for this plant it has been named *Apiaſtrum*, *Meliſſa*, *Meliſſophyllum* and by contraction *Meliſſophyllum*, and was directed by the ancients, among other herbs, to be rubbed upon the kive, to render it agreeable to the ſwarm. It is known by its Greek name of *Meliſſa* in all the languages of Europe, except the Daniſh, in which it is *Hiertensfryd*, and in Engliſh *Bawme*, *Baum*, *Bauke* or *Balm*.]

Mr. Miller makes a diſtinct ſpecies of the *Roman Baum*, which grows naturally about Rome, and in other parts of Italy. The ſtalks are ſlender, the leaves much ſhorter, the whole plant hairy, and of a ſtrong diſagreeable odour. The flowers grow in whorls, ſitting pretty cloſe to the branches, and are ſmaller than thoſe of the common ſort.

2. This alſo has a perennial root, and an annual ſtalk, riſing about a foot high. Leaves in pairs at each joint, an inch and half long, and three quarters of an inch broad, ſerrate, of a lucid green on their upper ſide, and whitiſh on the under. Single pedunculs come out from the axils, half an inch long, and dividing into two ſmaller ones, each ſuſtaining two flowers upon ſhort ſeparate pedicels. The flowers are large, of a purple colour. It flowers in june, and the ſeeds ripen in auguſt.

Native of Tuſcany, Auſtria, [Germany and the South of France. Cultivated in 1640, according to Parkinſon.—The leaves, when bruiſed, have the ſmell of garden Baum. There is a variety of it with white, and another with red flowers, both much inferior to the purple: it alſo has variegated leaves, as the common garden Baum [c].

3. Root perennial. Stem upright, four-cornered, woolly. Leaves in pairs, petioled, ovate-acuminate, hairy, dotted, very ſlightly ſerrate, much larger than thoſe of M. Nepeta. Pedunculs generally ſhorter than the leaves, ſometimes as long, and near the ends of the branches longer; three-forked, the lateral arms forked. Flowers twice as large as thoſe of M. Nepeta. Calyx with thirteen ribs, ſhort hair, and ſhining globules; ſegments fringed, and the mouth cloſed with long hairs; teeth pointing upwards after the corolla falls off, the three upper equal, the two lower longer and more pointed. Tube of the corolla beſet within with white club-ſhaped hairs: upper lip lilac-coloured within; lower lip pale within, but marked with three round dots, and a few ſhort ſtreaks of a deeper hue. Anthers double, purple; pollen whitiſh. Germs on a glandular receptacle. One ſegment of the ſtigma much longer than the other, and hooked [a].

Native of many parts of Europe, Italy, Spain, France, Switzerland, Auſtria, England, by the ſides of roads and corn fields. It flowers in auguſt.

4. Root perennial, ſomewhat oblique, crooked, round, woody, brown. Stems woody, divided juſt above the baſe into branches, which are from one to two feet in length, aſcending, obſcurely quadrangular, reddiſh towards the baſe, beſet with ſoft horizontal hairs. Leaves in pairs, rather remote, ſcarcely an inch long, on ſhort petioles, ſpreading, ſlightly keeled, reflex at the point, broad ovate, ſubcordate, bluntiſh, ſerrate, the margin rolled back, and ſlightly waved, wrinkled, ſoft, villoſe on both ſides, pale green, with pellucid dots. Flowers in whorls, very ſmall, pale blue, before they expand yelloviſh. Whorls halved, much longer than the leaves, few-flowered. Bractes few, ſmall, awl-ſhaped, one pair at each diviſion. Common pedunculs two, dichotomouſly branched, bearing four or ſix flowers, the laſt generally three flowers, the two outer of which have a pair of bractes, but the middle one is naked. Pedicels unequal, upright. Calyx with fifteen ſtreaks or ribs, beſet on the outſide with ſhort hairs and ſhining glands, ſmooth within, but cloſed at the mouth with long hairs; the three upper teeth equal, the two lower longer, equal, and more pointed; the ſtreaks and teeth of a brown purpliſh colour. Corolla longer than the calyx, ſlightly hairy: upper lip deeply emarginate, plaited at the back; lower lip beſet at the baſe with white club-ſhaped briſtles; lateral ſegments ovate, the middle one kidney-ſhaped, and marked on the inſide with reddiſh purple ſpots. Anthers two-celled, violet-coloured; pollen white. Germs ovate, on an orange-coloured receptacle. Style purpliſh [b].

Native of many parts of Europe, Italy, France, Switzerland, England; with us it chiefly affects dry chalky ſoils, by road ſides and in uncultivated places; flowering in auguſt, or from july to ſeptember.

It is ſometimes confounded with the preceding ſpecies.] Mr. Miller ſays, the ſtalks are longer and bend towards the ground; the leaves larger, more indented on their edges, and having a very ſtrong ſcent like Pennyroyal; the whorls of flowers ſet cloſer together. He appears from this not to have diſtinguiſhed theſe plants rightly. [The leaves and flowers are certainly ſmaller in this; the former more hoary; the whole plant is hairy. Krocker remarks, that the piſtil extends much more beyond the corolla than in the preceding ſpecies.

Both theſe ſeem to have been uſed indifferently in the old practice of medicine under the name of *Cala-*

[a] Krocker. [b] Woodville.

[a] Curtis. [b] Withering, Woodw. M. S. Relhan. [c] Curtis, Withering.

mintha. They have a ſtrong aromatic ſmell, approaching to that of Pennyroyal, and a moderately pungent taſte, ſomewhat like Spearmint; but warmer. Infuſions of the leaves were given as tea in weakneſſes of the ſtomach, flatulent cholics, and uterine obſtructions[1].]

5. Stems ſlender, a little woody. Leaves ſmall, roundiſh, hoary. Flowers ſmall and white, appearing in June. The ſeeds ripen in autumn. This ſpecies ſeldom continues more than two or three years.

[It bears ſome reſemblance to M. Nepeta. Stem humble, about a hand in height, ſtraight, very dark purple. Leaves ovate, ſparingly and bluntly ſerrate. Whorls many, compoſed of one-flowered leafleſs pedunicles, terminating the branches like a raceme. Bractes lanceolate. Calyxes brown. Corollas purpliſh white[2].

Native of the South of Europe. Cultivated by Mr. Miller in 1731[3].]

6. Stems ſlender, ſhrubby, about nine inches long, putting out ſmall, oppoſite ſide-branches. Leaves ſmall, hoary, ovate-acuminate, having much the ſame appearance with thoſe of Marum. Flowers in whorled ſpikes at the end of the ſtalks: they are ſmall and white; appear in July, and the ſeeds ripen in autumn. The whole plant has a ſtrong ſcent of Pennyroyal, and is of a ſhort duration.

[According to D'Aſſo, the ſtems are hoary and a foot high; the leaves ovate-rhomboidal, tomentoſe: flowers ſmall, pale purple.

It was cultivated in 1752, by Mr. Miller[4].]

PROPAGATION AND CULTURE.

1. Garden Baum is eaſily propagated by parting the root in October, time enough for the offſets to be eſtabliſhed before the froſts come on. The roots may be divided into ſmall pieces with three or four buds to each, and planted two feet apart in beds of common garden earth. The only culture they require is to keep them clean from weeds, and to cut off the decayed ſtalks in autumn, then ſtirring the ground between them.

The other ſorts may be increaſed and treated in the ſame manner.

5. If the ſeeds of this be permitted to ſcatter, there will be a ſufficient ſupply of young plants.

6. This may be increaſed by ſeeds, or by cuttings, planted in any of the ſummer months, and ſhaded from the ſun. On a warm border they will frequently live through the winter; but it is prudent to keep a plant or two in pots, ſheltered under a frame, in winter.

MELITTIS. *(From μελισσα, a Bee: uſed by Pliny as ſynonymous with Meliſſa.)*

Lin. gen. n. 731. *Reich. n.* 789. *Schreb. n.* 985. *Juſſ.* 116.

Claſſ. 14. 1. Didynamia Gymnoſpermia.

Nat. order of *Verticillatæ*, *Labiatæ*, Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, bell-ſhaped, round, ſtraight, with a two-lipped mouth. *Upper lip* higher, emarginate, acute; *lower* ſhorter, bifid, acute, with the diviſions gaping.

COR. one-petalled, ringent: *tube* much narrower than the calyx: *opening* ſcarcely thicker than the tube: *upper lip* erect, roundiſh, entire; *lower* ſpreading, trifid, blunt, middle ſegment larger, flat, entire.

STAM. *Filaments* four, awl ſhaped, under the upper lip, the middle ones ſhorter than the two outer. *Antheræ* converging by pairs in form of a croſs, bifid, blunt.

PIST. *Germ* blunt, four-cleft, villoſe. *Style* filiform, the length and ſituation of the ſtamens. *Stigma* bifid, acute.

PER. none. *Calyx* unchanged, containing the ſeeds at the bottom.

SEEDS four.

OBS. *The lower lip of the calyx is ſometimes crenated.*

[1] Lewis. [2] Linn. [3] Hort. Kew. [4] Ibid.

ESSENTIAL CHARACTER.

Cal. wider than the tube of the corolla. *Cor.* upper lip flat, lower crenated. *Antheræ* croſs-wiſe.

2. Melittis japonica.
Thunb. in Linn. tranſ. 2. 328.
Leaves alternate ovate obtuſe unequally ſerrate, calyx villoſe.]

DESCRIPTION, &c.

1. Root perennial, ſending up in the ſpring three, four or more ſtems, a foot and half high, [or more, upright, with a few branches at the baſe. The whole plant is hairy. Leaves oppoſite, petioled, ovate, elliptic, or ovate-lanceolate, ſomewhat pointed, unevenly and bluntly ſerrate, the ſerratures terminating in purpliſh glands, ſlightly villoſe, wrinkled; petioles channelled above, hirſute, united at the baſe. Flowers large, handſome, growing chiefly on one ſide, in half whorls about ſix flowers together. Pedunels round, ſomewhat hairy, axillary, the length of the petioles. Calyx ſomewhat inflated, veiny, ſmooth except the veins which are ſomewhat hairy: border on the upper ſide turned outwards like a ſpout, with a lanceolate ſegment on each ſide, the lower lip cut off and finely ſerrate: but the diviſions of the lips are inconſtant. Corolla ſlightly villoſe, white ſtained with purple; the middle ſegment of the lower lip full purple edged with white, and the edge finely notched. Filaments villoſe, ſhorter than the corolla. Seeds of a blackiſh colour[5].

Mr Curtis remarks, that the cruciform appearance of the anthers ought not to form a part of the eſſential character, being common to many of the didynamous plants; we may add, that it is a character which is apparent only for a ſhort time.

He remarks farther, that moſt authors deſcribe the Melittis as having an unpleaſant ſmell: the freſh herb when bruiſed partakes of the ſcent of Balm, and of ſtinking Horehound (Ballote); but when dried it becomes delightfully fragrant: the flowers when they firſt open are odoriferous.

Native of ſeveral parts of Europe: with us in the weſtern parts of the kingdom only, as in Devonſhire, about Totnels, Barnſtaple, &c. Hampſhire, in the New Foreſt; Pembrokeſhire, about Haverford Weſt; in woods and ſhady places. It flowers in may or june.

β. Cluſius mentions a variety in all reſpects ſmaller, the leaves more like thoſe of Lamium purpureum, ovate and heart-ſhaped, or at leaſt more inclining to that figure than our plant; the flowers are not ſo large as ours; they are uſually of a pale red, and ſometimes white. It is a native of Switzerland, Auſtria, &c.

Much honey is ſecreted from a gland that encircles the baſe of the germ; hence this is a favourite plant with bees, and it accords well with its name Melittis[6].]

2. Stem upright, villoſe, ſimple, a ſpan high. Leaves petioled doubly ſerrate, villoſe, ſpreading, a finger's length. Flowers peduncled, ſolitary in the axils of the leaves. Peduncle rough-haired, an inch long. Calyxes ſtrigoſe-hirſute, drooping[7].

[5] Curtis, Withering. [6] Curtis. [7] Thunberg.

Native

Native of Japan. When Thunberg publiſhed his Flora Japonica he was not aware that this is different from the European plant.

PROPAGATION AND CULTURE.

1. This is a handſome plant, continuing in flower three weeks or a month, if the ſeaſon is not very hot. As it rarely produces good ſeeds in the gardens, it is uſually propagated by parting the roots; but where the plants are intended for ornament, the roots ſhould not be diſturbed oftener than every third year; nor ſhould they then be divided into ſmall parts, leſt thereby they ſhould not flower the firſt year. The beſt time to remove and part the roots is the beginning of october, that they may have time to get root before the froſt comes on. They ſhould have a loamy ſoil and an eaſt expoſure, where the plants will thrive and produce flowers in plenty.

DESCRIPTIONS, *&c.*

There are ſome ſhrubby, others herbaceous, flowers axillary and terminating, ſometimes glomerate [a].

1. Stem ſhrubby at the baſe, branched, a foot high. Branches depreſſed, diffuſed, aſcending, ſimple, ſmooth. Leaves alternate, ovate, acuminate, ſerrate, nerved, ſmooth. Petiole ſhorter than the leaves, ſomewhat erect, ſlender. Flowers peduncled, ſubumbelled. Peduncles lateral, oppoſite to the petioles, ſolitary, the length of the petioles, three-flowered. Corollas ſmall, blood-red, frequently cloſed. Calyx five-toothed; teeth erect, lanceolate, acute. Claws of the petals yellow at the baſe; border ſuberect, entire, blunt [b]. Capſule membranaceous, vaſcular-netted, from a ventricoſe baſe riſing into a ſhort pyramid, having five narrow wings at the corners produced near the baſe into a horizontal dagger-point: the valves open along theſe wings, and are accompanied within by a middle ſeptum. Seeds two, ſeldom only one, ovate, acuminate downwards, convex on one ſide, on the other angular with a longitudinal white line, ſmooth, of a brown ruſt-colour; faſtened by a very ſhort umbilical chord to the central margin of the ſepta or partitions [c]. According to Swartz the ſeeds are ſolitary and oblong—according to Miller, ſolitary, and angular.

Swartz aſſures us, that M. dominicenſis of Jacquin certainly differs from this, the ſtem being four feet high, the leaves two inches long, &c. If ſo, M. pyramidata of Miller is not the ſame with that of Swartz, for he deſcribes it as four or five feet high, and ſays that the flowers are of a pale fleſh-colour.

Browne deſcribes it as a very elegant little plant, commonly ſhooting to the height of three feet or more, ſo ſlender and weak as generally to require ſome ſupport. The umbels of flowers are uſually placed pretty near, and each has five or ſix rays, on a common peduncle.

Native of Brazil and Jamaica. Cultivated by Mr. Miller in 1768.

2. This is an upright ſhrub, little branched, only three feet high in open rocky ſituations, but ſeven feet high in woods. Leaves oblong-ovate, tooth-ſerrate, acute, tomentoſe on both ſides, alternate, petioled, an inch and half long, with a ſtipule on each ſide. Common peduncles ſolitary, ſuſtaining in an umbel at top about five flowers with roſe-coloured corollas. Petals obovate, blunt, a little longer than the calyx, flat, erect, with a ſpreading border, the claws coaleſcing with the body of the filaments. Filaments the length of the corolla. Styles ſhorter than the ſtamens. Seeds one or two, angular [d].

According to Swartz, it is eaſily known from the preceding, by its being a ſhrub often a fathom in

[a] Juſſieu. [b] Swartz. [c] Gærtner. [d] Jacquin.

height,

height, with rod-like branches having a brown bark: leaves ſoft crenate, plaited, tomentoſe: peduncles umbelled, many-flowered: flowers larger, purple. Browne ſays, that the leaves are whitiſh, and the flowers of a light fleſh-colour.

Native of Jamaica, Martinico, St. Martin's and other iſlands of the Weſt Indies.

Swartz ſuſpects that M. domingenſis of Jacquin, which has been generally ſuppoſed to be the ſame with M. pyramidata of Linneus, may be a variety of this ſpecies.

3. This is a ſhrub with a purpliſh bark, and alternate, villoſe-tomentoſe, hoary branches. Leaves diſtant, ſcarcely an inch long or ſmaller, the younger ones tomentoſe on both ſides, ſoft, hoary, plaited, when older ſmoother above and marked with lines. Petioles ſhort, tomentoſe, hoary. Stipules ovate, hairy on the outſide, ſmooth within, one-third of the length of the petiole. Peduncles axillary, ſolitary, the length of the petiole, hirſute. Pedicels umbelled, uſually five, one-flowered; ſeldom ſingle, two-flowered: the length of the peduncle. Bractes briſtle-ſhaped, minute, deciduous, at the baſe of the pedicels. Calyx ſimple; ſegments lanceolate, hirſute, ſhorter by half than the corolla. Germ hirſute. Capſule oblong, five-cornered, hoary, twice the length of the calyx, terminated by the ſtyles, which are hirſute, and rounded at the angles.

Native of South America, where it was obſerved by von Rohr [a].

4. This riſes with a ſhrubby ſtalk five or ſix feet high. Leaves angular, reſembling thoſe of the Currant buſh. Flowers produced ſingly from the ſide of the ſtalk; they are of a fleſh colour, and in ſhape like thoſe of the ſmall-flowering Mallow. Capſules five-cornered, rough, incloſing five Mallow-ſhaped ſeeds.

[Browne ſays, it riſes commonly to the height of two or three feet, throwing out a few ſlender flexile branches on all ſides: the leaves ſpread themſelves every day about noon, to receive the heat of the ſun more freely, but as the air grows cooler, they generally riſe upright, and ſtand almoſt parallel to the ſtem or branches; this mechaniſm of the leaves is greatly forwarded by the knee in the footſtalk of each. It is found in many parts of Jamaica.] According to Miller, it was diſcovered at the Havannah, by Dr. Houſtoun.

5. Stem woody, four feet high, covered with brown hairs, and ſending out a few long ſlender branches, on the lower parts of which are leaves an inch and half long and three quarters of an inch broad, ſlightly ſerrate, and having many longitudinal veins: the upper parts have no leaves for more than a foot in length, and from their ſides come out peduncles two inches long, ſuſtaining ſeveral ſmall yellow flowers in cluſters, having hairy calyxes, cut at the top into ſeveral acute ſegments.

Found in South America by Dr. Houſtoun: [in Jamaica by Swartz.

6. This is a perennial, upright, ſmooth plant, with ſtiff branches. Leaves ſmooth, ovate-oblong, ſerrate, ſublobate at the baſe on both ſides, petioled. Racemes ſeveral in bundles, divaricating [b].

Natives of the Eaſt Indies.

7. This is a ſhrub, with round, alternate, ſmooth, purple branches, a little flexuoſe. Leaves two inches long and more, ſmooth on both ſides, nerve-veined above, with the veins purpliſh underneath, ſerrate, acute. Petioles pubeſcent, ſhort. Stipules lanceolate, briſtle-ſhaped, the length of the flowers, deciduous. Flowers conglomerate in the axils, ſeſſile, ſmall. Bractes ovate, the length of the flowers. Segments of the calyx ovate-acuminate. Corolla longer than the calyx [c].

Native of Jamaica and other iſlands of the Weſt Indies.

8. Native of Jamaica, where it was found by Swartz.

9. This is an annual plant, hardiſh and diffuſed, with rugged, rod-like branches. Leaves bluntiſh, naked, plaited, ſerrate. Flowers terminating. Corollas pale purple with a yellow bottom [d].—Native of the Eaſt Indies. Cultivated in 1732 by James Sherard, M. D. [e] from ſeeds ſent over by Jo. Phil. Breynius [f].]

10. This is an annual plant with trailing ſtalks, and ſmall Betony-ſhaped leaves. The flowers and fruit are produced in cluſters at the ends of the branches.—Native of the Eaſt Indies.

[11. This is ſmooth, but the peduncles are aſh-coloured with a very fine down. The leaves very much reſemble thoſe of the ninth ſort, but are much larger. Panicles on long peduncles and branched. Flowers large [g].

Native of the iſlands of Tanna and Tongataboo in the South Seas.

Viſenia indica of Gmelin; Viſenia umbellata of Houttuyn is the ſame as this [h].]

PROPAGATION AND CULTURE.

Sow the ſeeds on a hot-bed, and when the plants come up treat them in the ſame manner as is directed for SIDA. The ſhrubby ſorts may with care be preſerved through the winter in a ſtove, whereby good ſeeds may be obtained, for they ſeldom ripen their ſeeds well the firſt year, unleſs the plants are brought forward early in the ſpring, and the ſummer proves warm. The other ſorts generally ripen their ſeeds the ſame year they are ſown.

[MELOCHIA. See *Waltheria*.

MELODINUS. (*So named by Forſter, from μηλον an apple, and δινω to turn round; this plant bearing a round fruit like an apple, and having a twining ſtem by which it climbs trees.*)

Lin. gen. Schreb. n. 425. *ſuppl.* 23. *Forſt. gen.* 23. *Juſſ.* 148.

Claſſ. 5. 2. Pentandria Digynia.

Nat. order of *Contortæ. Apocineæ.* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-parted, permanent: *leaflets* ovate, lying over each other at the edge.

COR. one-petalled, ſalver-ſhaped. *Tube* cylindrical, three times as long as the calyx. *Border* five-parted, flat: *ſegments* ſickle-ſhaped, crenulate, twiſted to the right, ſhorter than the tube.

Nectary in the mouth of the tube, ſtellate: *ſegments* five, cloven, lacerated.

STAM. *Filaments* five, awl-ſhaped, very ſhort, in the middle of the tube. *Anthers* ovate.

PIST. *Germ* globular, ſuperior. *Style* round, the length of the calyx, bipartile. *Stigma* conical, acute.

PER. *Berry* fleſhy, globular, many-ſeeded: with a fleſhy partition.

SEEDS numerous, ovate-roundiſh, flatted a little, neſtling.

ESSENTIAL CHARACTER.

Contorted. Neſt. in the middle of the tube, ſtellate. *Berry* two-celled, many-ſeeded.

SPECIES.

1. Melodinus ſcandens.

Lin. ſyſt. 256. *ſuppl.* 167. *Forſt. flor. auſtral. n.* 125.

DESCRIPTION, *&c.*

This is a very ſmooth ſhrub with a climbing ſtem. Leaves oblong-ovate, veined, quite entire, very ſmooth, oppoſite. It has a great affinity with Rauwolfia.

Native of New Caledonia [i]. Found there the 13th of ſeptember, 1774.

MELON. See *Cucumis.*

SPECIES.

1. Melothria pendula.
Lin. ſpec. 49. *ſyſt.* 82. *Reich.* 1. 94. *Willd.* 189. *hort. cliff.* 490. *upſ.* 15. *Gron. virg.* 10. *Knipb. orig. cent.* 4. *n.* 49. *Swartz obſ.* 26. *Brown. jam.* 124. *Pluk. phyt. t.* 85. *f.* 5. *Sloan. jam.* 1. 227. *t.* 142. *f.* 1. (Cucumis). *Plum. ſpec.* 3. *ic.* 66. *f.* 2. (Bryonia).

DESCRIPTION, *&c.*

1. This plant grows wild in the woods in Carolina, Virginia, and alſo in many of the iſlands in America; it creeps upon the ground with ſlender Vines, having angular leaves, ſomewhat reſembling thoſe of the Melon, but much ſmaller. Theſe Vines ſtrike out roots at every joint, which faſten themſelves into the ground, and thereby a larger ſhare of nouriſhment is drawn to the plants, by which means their ſtalks extend to a great diſtance each way, and cloſely cover the ground. The flowers are very ſmall, in ſhape like thoſe of the Melon, and of a pale ſulphur colour.

The fruit, in the Weſt Indies, grows to the ſize of a Pea, of an oval figure, and changes black when ripe; theſe are by the inhabitants ſometimes pickled when they are green.

In England the fruit are much ſmaller, and are ſo hidden by the leaves, as to render it difficult to find them.

[Peduncles filiform, lax, one-flowered [a]. Swartz ſays, that it always appeared to him to be monoecous, inſomuch that it differs from Cucumis only in having a berried fruit, which has exactly the ſame taſte with a green Cucumber.

Stem angular, ſtriated, filiform, weak, ſlender, even, two feet long, annual. Leaves flat, rugged, five-lobed, the front lobe divided with deeper ſinuſes, cordate at the baſe, the margin very ſlightly toothletted, on lax petioles, bent in at the baſe, alternate, remote, the length of the leaf; a very ſimple ſolitary long tendril comes out cloſe to the petiole. Peduncle axillary, ſolitary, briſtle-ſhaped, very long, one-flowered. A branch from the ſame axil, very like the ſtalk. Corolla yellow. Fruit the ſize of a Peony ſeed, tubercled, pendulous [b]. Browne ſays it is remarkable for the ſlender ſtalk and ſmall black oval berries.

It was cultivated in 1759, by Mr. Miller [c].]

PROPAGATION AND CULTURE.

The plants will not grow in the open air here, but the ſeeds muſt be ſown upon a hot-bed, and if the plants are permitted, will ſoon ſpread over the ſurface of a large bed; and when the fruit is ripe, if it ſcatters the ſeeds, the plants will come up where the earth happens to be uſed on a hot-bed again, and if they are ſupplied with water, will require no farther care. This plant is in ſome gardens preſerved for the ſake of variety, but is of no uſe.

Leaves ovate acute, umbellets compound naked.

DESCRIPTIONS, *&c.*

1. This is a tree with round branchlets. Leaves ſmooth, oppoſite, quite entire, on very ſhort petioles. Peduncles axillary, oppoſite, ſolitary, ſhort, terminated by a head of flowers. Allied to Vaccinium, but the appearance is different.—Native of Ceylon [a].

2. This is a large tree, with round branches. Leaves oppoſite, quite entire, half a foot long. Peduncles alternate, four or five-cleft, with many-flowered pedicels. Anthers incumbent, all curved, perhaps in drying.—Native of the Eaſt Indies. Communicated by Koenig [b].

3. Berry inferior, globular, crowned with the calyx permanent tubular eight-ſtreaked within and ſpreading into a repandly quadrangular margin, or not ſtreaked and merely four-toothed, one-celled, ruſeſcent. Cuticle coriaceous, thin. Pulp watery, fugacious. Seeds two or only one, globular, very ſmooth and even, ſhining, pale cheſtnut coloured, with a depreſſed point at top.

β. Berry ſubglobular, twin, crowned with the bluntly four-toothed calyx, one-celled, two-ſeeded, ſmooth, of a pale ſtraw-colour. Bark becoming very thin and as it were papery by age. Tube of the calyx ſmooth and even within, without any veſtige of ſtreaks. Seeds two, hemiſpherical, very ſmooth and even, ſhining, dun-coloured. The berries are much ſmaller, with a thinner ſmooth bark, the calyx is not at all ſtriated within, the ſeeds are commonly in pairs, and the peduncles of the berries are longiſh and manifeſtly corymbed [c]. Gærtner affirms that this is certainly Samara læta of Linnæus; in which he is probably miſtaken.

4. Trunk very irregular in ſhape and ſize, covered with a dark-coloured ſcabrous bark. Branches numerous nearly erect. Leaves oppoſite ſhort-petioled, ovate, ſmooth, ſhining, firm, entire, with ſcarcely any veins; from three to four inches long, and from two to three broad. Umbellets many, compound, ſmall; from ſcabrous elevations, where the leaves ſtood, over the old woody branches. Peduncles common and partial, four-ſided. Pedicels round, coloured. Seldom more than one ſeed comes to perfection, though in the germs the rudiments of many are to be ſeen.

It is a very common ſmall tree or large ſhrub, in every jungle on the coaſt of Coromandel. It flowers about the beginning of the hot ſeaſon. The ripe

[a] Linn. zeyl. [b] Retzius. [c] Gærtner.

berries are eaten by the natives; they have much pulp of a bluish-black colour, and of an astringent quality.

MENISCIUM. (*So named from the fructifications being in the form of a little Creſcent.*)

Lin. gen. Schreb. n. 1630. Aſplenium. *Jacqu. collect.* 2. *t.* 3. *f.* 2.

Claſſ. 24. 2. Cryptogamia Filices, or Ferns.

GENERIC CHARACTER.

Capſules heaped in creſcents, interpoſed between the veins of the frond.

SPECIES.

1. Meniſcium reticulatum.

Aſplenium ſorbifolium. *Jacqu. collect.* 2. 106.

Polypodium reticulatum. *Lin. ſpec. ed. Reich.* 4. 417.

Filix. *Plum. amer.* 6. *t.* 9. *fil.* 92. *t.* 110. *Pet. fil.* 10. *t.* 6.

DESCRIPTION, *&c.*

Root fibrous, black. Fronds ſeveral, pinnate, four feet long. Stipe black, grooved in front, angular, brown, appearing ſomewhat villoſe when magnified. Pinnas very many, alternate with an odd one, on ſhort petioles, from an ovate baſe long lanceolate, acuminate, crenate, a little ſickle-ſhaped at the end, ſmooth above, ſomewhat villoſe along the nerves underneath, from ſix to nine inches long, an inch or an inch and half wide. The midrib is prominent at the back, and at a very obtuſe angle puts forth on both ſides towards the edges numerous parallel nerves, which are alſo prominent: theſe are connected by ſeveral arched veins; whence the pinnas ſeen againſt the light appear like beds in a parterre. On theſe veins are placed as many arched-oblong, parallel, dark-ruſous fructifications, compoſed of very minute ſhining globules, thoſe which are next the midrib larger. They are not ſo cloſe upon the whole as in moſt of the Aſpleniums: nay they ſometimes exhibit diſtinct globules thinly placed.—Native of Martinico *, Brazil, &c.]

MENISPERMUM. (*From* Μην *the Moon, and* Σπερμα *a ſeed. The ſeed being ſhaped like a creſcent.*)

Gærtn. fruct. 1. 219.

DESCRIPTIONS, *&c.*

Flowers in spikes or racemes, supraaxillary or terminating, each furnished with its bracte [a].]

1. Root thick, woody. Stems many, climbing, becoming woody, and rising to the height of twelve or fourteen feet, twisting themselves about the neighbouring plants for support. Leaves large smooth, with the footstalk almost in the middle, and a hollow there on the upper side. The flowers come out in loose bunches from the side of the stem; they are of an herbaceous colour, small, and composed of two rows of oblong oval petals. Stamens very short, ten in the male flowers. Germs and berries two, in the female flowers, channelled, each containing one seed.

[The stem twines in a direction contrrary to the sun's apparent motion, and is smooth and even. Leaves rounded-cordate, five-angled, smooth and even, acuminate. Peduncle two-racemed, supraaxillary, nodding, shorter than the petiole [b].—Native of Virginia, Canada, and Siberia. Cultivated in 1713 by Bishop Compton. It flowers in june and july [c].]

2. This differs from the preceding in the shape of the leaves, which are angular and sometimes heart-shaped, but not peltate, having the footstalk at the base. The stems become woody, and rise nearly as high as those of the first sort. The flowers and berries do not differ from them.

[Stems round, slender, twining. Leaves alternate, bright green, the form, colour and consistence of Ivy leaves, on the upper part of the stem entire, as on old Ivy; on the middle and lower part not unfrequently angular, as in young Ivy; although they have very slender hairs on them, yet they have the appearance of being smooth and shining, especially the younger leaves, for the older ones are subhirsute and less shining; underneath they are of a paler green. The stems and petioles are villose. Flowers in small naked spikes from the upper axils, composed of six short, blunt, whitish petals. The germ and style appear to consist of five or six horns. Berries three, four or five together, black, small, moderately compressed, wrinkled. Seeds compressed, hard, wrinkled.—Native of Virginia and Carolina [d]. Cultivated in the Eltham garden about 1732.

3. Stem herbaceous, twining, striated with several angles, smooth in all parts, simple. Leaves alternate, acuminate, the point blunt and subretuse, glaucous underneath, the nerves running out from the centre, a hand in length. Petioles twining, grooved, scarcely twisted, a finger's length and more. Flowers axillary, decompoundedly subumbelled, pedicelled, dioecous. Peduncles striated, an inch long. Pedicels striated-angular, umbelled, scarcely a line in length. Berries two, obovate-subreniform, compressed, most at bottom, united on both sides by a large oblong groove, muricated, one-valved, one-celled. Seed white.—Native of Japan [e].]

4. This differs from the second sort in its branches not becoming woody as in that. The stems are herbaceous, the leaves entire and hairy, and not more than half so large as those of the second, nor is the plant so hardy, so that it does not produce flowers in England, unless the season prove very warm.—Native of Carolina. [Introduced in 1765 by Mr. John Cree [f]. Mr. Miller however cultivated this with the first and second sorts in 1759.

5. Drupes one, two or three, ovate-globular, fleshy, scarlet, smooth: shell subglobular, bony, somewhat rugged, gibbous on one side, compressed into an angle on the other, one-celled. Receptacle fungous, subcrose, semiglobular, inserted by a thick peduncle into the belly of the shell. Seed solitary, bullate, smoothish, rufescent, with a wide perforation for the receptacle to pass through it, marked with a ridge within [g]. This is not the *Natsjatam* of the Hortus Malabaricus.

The twisting stems are usually the thickness of the human arm or thicker, irregular, and covered with a thick, lacerated, wrinkled bark: the branches terminate in strong simple tendrils. Leaves alternate, firm, a span long, deep green above, very yellow and lanuginose underneath, on long stout petioles, bent in or flexuose near the base. Bunches of flowers a foot and half long, dividing into several lateral ones. Petals six, white, reflex. The flowers have an unpleasant smell. Fruit in bunches like grapes, but smaller; first white, then red, and finally blackish purple; usually two or three, seldom four together, on a thickish, pyramidal, wrinkled peduncle. Pulp soft. Stone round, like that of a Cherry, but a little larger, wrinkled and granulated, having a fissure or aperture on one side, and a white bifid kernel within. These berries are used to intoxicate fish, birds, &c. in order to take them, being made up into a paste [h].—Native of the East Indies.

6. Native of Bengal.

7. Stem twining, simple, all over smooth. Leaves alternate, roundish-ovate, deeply cordate, very long pointed, entire, nerved, somewhat netted, glaucous underneath, smooth, a hand in length and breadth. Petioles loose, round, striated, a little shorter than the leaf.—Native of Japan.

8. The whole of this plant is very finely villose. Stem round, twining, with alternate branches like the stem. Leaves alternate, on very short petioles, the lowest triangular-ovate, the branch-leaves ovate, the uppermost orbiculate, blunt with a point, entire, an inch long, the upper ones gradually smaller. Flowers axillary, panicled, dioecous.—Native of the East Indies and Japan.

9. Native of the East Indies. The heads on Plukenet's figure are galls of some insect.

10. The whole plant is smooth. Leaves petioled, mucronate, the lower ones emarginate. Petioles two lines in length. Peduncles scarcely so long. Calyx six-leaved. Corolla six-petalled. Berries kidney-form, two with the rudiment of a third. Stamens six. Pistils three. In habit so like M. hirsutum, that there is scarcely any limit between them [i].—Native of Arabia.

11. Native of the East Indies. Perhaps it may be only the female of the ninth species, which varies much in the form of the leaves [k].

12. Stem filiform, twining, little branched. All parts of the plant rough-haired and villose. Leaves alternate, acute with a long point, quite entire, nerved, paler underneath, an inch long. Petioles round, villose, reflex at the base. Flowers axillary, racemed, deciduous, dioecous. Peduncle round, very short. Pedicels smooth, one-flowered, scarcely half a line in length. In the male the perianth is three-leaved, very small, smooth, whitish; the segments round, concave: besides three leaves of the calyx, and often two others, very small like a calycle. Corolla three-petalled, bell-shaped, white. Petals rounded, blunt, entire, concave, half a line in length. Nectary six leaves, within the petals and alternate with them, linear, cloven at the top, white, the length of the corolla. Filaments fix, inserted into the leaves of the nectary, bent in at top, whitish, shorter than the nectary. Anthers round, yellow. In the female, the berry is globular, the size of a small pea. Seed single, globular, torulose, filling the berry.

Native of Japan, flowering in august and september [l]. Found also in the province of Kianang in China by Sir George Staunton.

13. Drupe berried, obovate, solitary, pubescent, hoary. Rind thin, becoming coriaceous, closely fastened to the shell; which is large, kidney-form or globular-flatted, bony, thick, crose on the outside, smooth within. Receptacle fungose-fleshy, from the base of the shell on a thick stalk, spread out into an irregular globe, filling the whole cavity of the seed, and diverging into various very irregular processes

[a] Jussieu. [b] Linn. spec. [c] Hort. kew. [d] Dillenius. [e] Thunberg. [f] Hort. kew.

[g] Gærtner. [h] Rumphius. [i] Vahl. [k] Dryander, M. S. [l] Thunberg.

received

received within the plaits of the albumen. Seed ſingle, ſubglobular, flatted a little, ſmooth on the outſide with a tranſverſe line, within hollow, with many turnings and windings, bullate, filled with the ſubſtance of the receptacle, having a wide perforation below. Skin ſingle, membranaceous, very thin, pale. Albumen of the ſame form with the ſeed, fleſhy like an Almond, thin, white, compoſed of two fleſhy laminæ, and diviſded into two leafy-compreſſed cells, in each of which each cotyledon reſides. Embryo almoſt the ſize of the albumen, inverted, green or yellowiſh. Cotyledons leafy, very thin, roundiſh and concave, but variouſly flexuoſe, perforated with many holes and as it were windowed by the impreſſions of the receptacle; ſo entirely ſeparated, that one inhabits the right and the other the left ſide of the ſeed, and both are oppoſite to each other. Radicle awl-ſhaped, very ſhort, ſuperior*. Native of Ceylon.

Gærtner remarks, that the ſpecies of this genus vary much in their number in the flower and fruit; but that they all not only agree in the poſition of the cotyledons, but differ from all other plants in having a diſtinct cell for each cotyledon.

Many of the ſpecies have only ſix ſtamens, and Willich has obſerved that many have three piſtils.]

PROPAGATION AND CULTURE.

1. 2. Theſe are eaſily propagated by laying down the branches in autumn. They will have made good roots by the following autumn, when they may be ſeparated from the old plant, and tranſplanted where they are deſigned to remain. Their branches being ſlender and weak, they require ſupport. If planted near trees, they will thrive better than in an open ſituation.

4. This may be propagated by parting the roots, which ſpread out on the ſide, to that part of them may be cut off every other year; the beſt time for doing this is in the ſpring, a little before the plants begin to ſhoot; theſe ſhould be planted in a warm ſituation and have a light ſoil, for in ſtrong land, where the wet is detained in winter, the roots are apt to rot; therefore if they are planted cloſe to a wall expoſed to the ſouth or weſt, their ſtalks may be faſtened againſt the wall, to prevent their trailing upon the ground; and in this ſituation the plants will frequently flower, and by having a little ſhelter in ſevere froſt, their ſtalks may be preſerved from injury.

MENTASTRUM. See *Hyſtropogon*.

MENTHA. (Menta of *Pliny*. *Muſhe of Theophraſtus*. *From a nymph of that name, daughter of Cocytus, fabled to have been changed into this herb by Proſerpine in a fit of jealouſy. DESCRIPTIONS, *&c.*

Root perennial, commonly creeping. Herb generally ſmelling very ſtrong. Flowers either in axillary whorls, or in whorls forming a ſpike at the top[a].

1. Stem upright, four-cornered with the ſides excavated, ſimple, a foot high, hiſpid with ſtiffiſh hairs. Spike very thick and cloſe. Branches ſhorter from the lower axils[b]. Calyx five-cleft. Corolla four-cleft. Filaments hairy[c].

Native of the Eaſt Indies.

2. Stems villoſe, branched, weak, a foot high, aſcending. Leaves ovate, the ſmaller ones lanceolate, villoſe and green on both ſides, acute, ſharply ſerrate, veined. Spikes very cloſe, about an inch in length, almoſt cylindric, on the branchlets uſually ſolitary, on the top of the ſtem ſeveral, one upright, the next below horizontal. Flowers ſmall. Calyx villoſe, with the border divided into five almoſt equal lanceolate-acuminate toothlets. Corolla pale, funnel-form, almoſt twice as long as the calyx; upper lip cordate or half five-lobed, lower divided into three ovate or oblong blunt ſegments; all violet-coloured in the middle. Filaments and ſtyle twice as long as the corolla. Anthers twin, violet[d].

[a] Jacqu. [b] Linn. zeyl. [c] Linn. mant. [d] Jacquin.

The wild plant is hoary all over, with very ſoft leaves, ſpikes two inches long formed of crouded whorls [a].

Native of Egypt.

3. The whole of this plant is ſmooth and herbaceous. Leaves an inch and half long, nerved, appearing dotted underneath when viewed with a magnifier. Peduncle terminating. Whorls eighteen-flowered, nine on each oppoſite peduncle, umbelled. Bractes linear, the length of the whorl. Stamens ſhorter than the corolla. Style longer [b].

Native of Egypt.

4. Stem herbaceous, upright, four-grooved, one foot high. Leaves in fours, oblong, blunt, ſmooth. Flowers very ſmall, in oblong, heaped, terminating ſpikes. Calyx five-cleft, acute. Corolla twice as long as the calyx, dilated at the baſe, pale violet almoſt white; border ſpreading, legments blunt, ſhort. Filaments longer than the corolla, ſurrounded with long hairs in the middle. Anthers very ſmall. Style equal to the ſtamens. Seeds roundiſh.

Native of Cochinchina [c].

5. Stem upright, four-grooved, branched at top, ſmooth at bottom, but hoary with down towards the top, almoſt wholly covered with leaves, a foot and half or two feet in height, ſometimes three feet, and according to Pollich even ſix feet. Leaves ſmooth above, whitiſh and tomentoſe underneath, or white-tomentoſe on both ſides, with ſlender ſharp ſerratures. Spikes terminating the ſtem and branches, oppoſite, the lower on longer, the upper on ſhorter peduncles, all hoary with cottony down, thick and cloſe with approximating whorls, an inch or an inch and half in length. Calyx hardly a line long, hoary. Corolla twice as long, pale purple. Filaments twice or thrice as long as the corolla [d]. It varies with filaments equal only to the corolla [e]. This circumſtance appears to me a very uncertain mark of ſpecific diſtinction.

Native of many parts of Europe, Denmark, Germany, Switzerland, France, England, in hedges, ditches, marſhy and watery places. With us in Lincolnſhire, Cambridgeſhire, Eſſex, Suffolk, Kent, &c.

6. Horſe-Mint or Water-Mint with a groſſer ſpike was found by Dale near Bocking in Eſſex.

6. This is very nearly allied to the preceding, but it is ſmaller and ſmoother, the leaves are not white, are narrower and more pointed; the ſpikes are thinner, and the corolla is purpliſh red [f].

Native of Germany, Switzerland, France, and England, in watery places and on the banks of rivers, as on the Thames, and near Exmouth in Devonſhire.

Mr. Miller has a variety, which he calls M. glabra (n. 2.) with ſmoother narrower leaves, very ſlightly ſerrated towards the points, which is cultivated in gardens with the other, and not diſtinguiſhed from it.

He has alſo another which he calls M. candicans, with ſhorter broader leaves, the ſerratures more acute, and the under ſides white. The ſtem divides more, and is therefore terminated by more ſpikes, the lower of which is interrupted. The ſcent of this is very like that of Garden Mint (M. viridis). This may perhaps be a variety of M. ſylveſtris.

This ſpecies not being ſo hot to the taſte as Peppermint, and having a more agreeable flavour than moſt of the others is generally preferred for culinary and ſome medicinal purpoſes. The leaves or tops are uſed in ſpring ſalads, and eaten dried as ſauce with lamb and in ſoups.

The preparations of Spear Mint are more pleaſant than thoſe of Pepper Mint, but perhaps leſs effeacious. This herb, as do the other ſorts, contains much eſſential oil, but of an odour leſs agreeable than that of Lavender or Marjoram. It is therefore leſs employed as a cephalic; but it acts very powerfully on parts to which it is immediately applied, and therefore conſiderably on the ſtomach. It acts eſpecially as an antiſpaſmodic, and therefore relieves pains and cholic ariſing from ſpaſm. It will alſo ſtop vomiting dependent on the ſame cauſe, but if it ariſe from an inflammatory irritation in the ſtomach itſelf, or in other parts of the body, it aggravates the diſeaſe. The infuſion of Mint in warm water agrees better with the ſtomach than the diſtilled water. The officinal preparations are an eſſential oil, a conſerve, a ſimple water, and a ſpirit. The conſerve is very grateful, and the diſtilled waters, both ſimple and ſpirituous, are generally thought pleaſant.

Lewis obſerves, that Mint is ſaid to prevent the coagulation of milk; and hence it has been recommended to be uſed with milk diets, and even in cataplaſms and fomentations for reſolving coagulated milk in the breaſts: upon experiment, the curd of milk, digeſted in a ſtrong infuſion of Mint, could not be perceived to be any otherwiſe affected than by common water; but milk, in which Mint leaves were ſet to macerate, did not coagulate near ſo ſoon as an equal quantity of the ſame milk kept by itſelf.

Lewis ſays that dry Mint digeſted in rectified ſpirits of wine, gives out a tincture which appears by day-light of a fine dark green, but by candle-light of a bright red colour. The fact is, that a ſmall quantity of this tincture is green, either by day-light or candle-light, but a large quantity ſeems impervious to common day-light; however when held between the eye and a candle, or between the eye and the ſun, it appears red: ſo that if put into a flat bottle it appears green, but when viewed edgewiſe red [g].

7. Stems from two to three feet high, erect, hairy or ſhaggy, the hairs pointing more or leſs downwards. Leaves ſomewhat cordate, rugged, ſtrongly and ſharply crenate or rather ſerrate, the teeth and points of the ſmall upper ones being often very taper: the under ſide is ſhaggy not hoary, and all the veins are fringed as it were with cloſe hairs. Spikes ſeveral, terminating, erect, ſharpiſh, not very denſely whorled: the bractes lanceolate, hairy, ſharp and projecting. Flowers reddiſh. Calycine teeth broad at the baſe. Stamens always much longer than the corolla.

Our plant is very near, if not the ſame, to what Linnæus intended for *crispa*, in the firſt edition of Species Plantarum; but it is not that of the ſecond edition and all other authors, which has never yet been found in Britain. Ours is alſo *M. ſpicata* γ of that firſt edition.

Native of ſeveral parts of Europe. With us it is rather rare; growing in waſte ground, generally where there is a moiſture; and flowering in auguſt and ſeptember. Shingham, Norfolk [h], near Faulkburn Hall, &c. Eſſex; Cambridgeſhire; Hornſey and Harefield church-yards, Middleſex; near Ruſs, Herefordſhire. Like ſeveral other ſpecies, it is found in the gardens variegated.]

8. Stems hairy, about the ſame height with common Spear Mint. Leaves deeply indented on their edges, waved and curled, light green. Flowers purple, growing in thick interrupted ſpikes at the top of the ſtalks. Calyx cut almoſt to the bottom. Style ſtanding out beyond the corolla.

[Stem branched very much, upright, eighteen inches and more in height. Leaves hirſute, ovate-lanceolate, ſeſſile or on a very ſhort petiole, ſharply toothletted, wrinkled, nerves prominent. Calyxes hirſute. Spikes ſhort, formed of interrupted whorls with ſmall leaves under each [i].]

Mr. Miller ſays that it was brought originally from Denmark, but that Linnæus fixes it as a native of Siberia. [It appears in ſome of the European Floras, but it is only or chiefly found there in gardens, as it is alſo in China and Cochinchina, where it is uſed in medicine.—It was cultivated in 1658 in the Oxford garden [k].

9. Roots long, branched, creeping under water. Stem branched, very generally purpliſh, rough with deflex hairs ſcattered all over it; there it however a denſe tuft of ſimilar hairs, between the inſertions of the foot-ſtalks, which are erect, and the hairs on the foot-ſtalks and leaves alſo point upwards or forwards. The degree of hairineſs throughout the whole plant

[a] Vahl. [b] Hedſon. [c] Loureiro. [d] Krocker. [e] Krocker, Villars, Linn. [f] Woodville and Withering. [g] Haller. [h] English Botany. [i] Hort. Kew.

vari-

varies extremely. Leaves on ſhortiſh foot-ſtalks, ſometimes almoſt ſeſſile, ſpreading, ovate frequently approaching to elliptical, pointed, ſerrate from a little above the baſe to near the tip, paler and moſt hairy beneath, eſpecially about the nerves. Flowers lilac-coloured, numerous, in a large round terminating head, which, when accurately obſerved, is found to be divided into three parts, and is accompanied, at a greater or leſs diſtance below it, by a pair, rarely more, of ſmaller axillary heads. Peduncles and calyx very hairy. Stamens generally longer than the corolla.

When out of the water it grows much ſmaller, more purple, with a ſimple head of flowers; which ſeems to be Hudſon's variety γ, though not very well drawn by Dillenius in Ray's ſynopſis.

Hudſon has conſidered this, perhaps rightly, as the ſame with *M. aquatica* ſ. *Siſymbrium* of John Bauhin, and Ray's Synopſis, which Dr. Smith believes to be *M. piperita* of Linneus, and which is deſcribed in Sir Joſeph Banks's manuſcripts by the name of *M. Siſymbrium*. M. aquatica of Linneus ſeems different from both.

M. hirſuta is very common in clear ditches, rivulets, and other watery places, growing ſometimes among large graſſes and reeds, ſometimes by itſelf. It flowers in auguſt [9].

10. This is not a rough-haired plant. Whorls terminating, cluſtered, forming a head or blunt ſpike. Stamens longer than the corolla. In the preceding ſpecies the leaves are more ſeſſile and hirſute. The piſtil is longer than the corolla, which is deeply four-cleft, and almoſt regular. Calyxes ciliate. They agree in the length of the ſtamens, and the general appearance [10].

Stem reddiſh towards the top, and ſet with a few briſtly hairs pointing downwards. Leaves ovate-lanceolate, a little hairy on both ſides, ſometimes woolly. Branches generally ſhorter than the leaves. Calyx coloured ribbed, hairy without, ſcored within; teeth not quite equal; glands ſemitranſparent. Corolla hairy without, pale red. Filaments half as long again as the corolla, nearly equal [11].

I have kept theſe deſcriptions ſeparate, becauſe Linneus's M. aquatica and ours may probably be different plants. Mr. Miller has two ſpecies, *M. aquatica*, n. 5. and *M. paluſtris*, n. 11.]

11. Our true Engliſh Pepper Mint has ſmooth purple ſtalks. The leaves are ſmaller than thoſe of Spear Mint; they are lanceolate, ſerrate, very dark green, with purple midrib and veins, and they are a little hairy on their under ſide. The ſpikes of flowers are ſhorter and thicker than thoſe of Spear Mint, and are broken or interrupted at bottom. The corolla is of a dark purple colour, and the ſtamens are longer than the corolla.

[Spikes terminating the ſtem and upper branches, conſiſting of from nine to twelve whorls. The lower whorls peduncled, diſtant. In external appearance it correſponds with *M. viridis*, for which it may eaſily be miſtaken; but in that the ſtem is taller, the leaves have ſcarcely any petioles and are narrower in proportion to their length, the ſpikes are longer and compoſed of more whorls. It ſeems to be diſtinct from *M. piperita* of Linneus [12].

Peppermint is found in watery places and by the ſides of rivulets in Hertfordſhire and Eſſex, between Newington and Hornſey.] Mr. Miller found it by the ſide of the river between Mitcham and Croydon in Surry. It flowers in auguſt.

[The ſtem and leaves are beſet with many very minute glands, containing the eſſential oil, which riſes pleniſully in diſtillation [13]. Peppermint has a more penetrating ſmell than any of the other ſpecies, and a much ſtronger taſte, pungent and glowing like Pepper, ſinking as it were into the tongue, and followed by a ſenſation of coldneſs.

Its ſtomachic, antiſpaſmodic and carminative qualities render it uſeful in flatulent colics, hyſterical affections, retchings, and other dyſpeptic ſymptoms, acting as a cordial, and often producing immediate relief. The officinal preparations are an eſſential oil, a ſimple water, and a ſpirit. The Eſſence of Peppermint is an elegant medicine, and ſeems to be the rectified oil diſſolved in ſpirits of wine [14].

12. Root throwing out long creeping horizontal ſhoots, and one erect hairy ſtem, furniſhed all the way up to the flowering part with ſhortiſh axillary leafy branches. Leaves ſharply ſerrate from near the baſe, veiny, clothed on both ſides with ſhort ſcattered hairs, and paler beneath; the baſe of the leaf runs down the foot-ſtalk. Flowers in axillary cluſters from many of the uppermoſt leaves, forming whorls, and each cluſter is more or leſs peduncled. General and partial peduncles thickly covered, eſpecially the ſummit of the latter juſt under the calyx, with white hairs pointing downwards like thoſe on the ſtem, but the calyx itſelf is clothed all over with hairs which point upwards, juſt as in *M. hirſuta*; by which it may be eaſily known from every variety of *M. gentilis*, the peduncles of which are always ſmooth, and the calyx hairy about the top only. Stamens ſhorter than the corolla; in Linneus's ſpecimens they are longer.

It is preſumed by Mr. Edward Forſter, jun. to be the *M. verticillata* of Ray's ſynopſis, having been found by him in the ſpot where it was marked to grow by Dillenius. Dr. Smith has determined the ſame plant to be M. ſativa of Linneus from his herbarium. He ſuſpects after all that this is no more than a worſted variety of M. hirſuta. It flowers in auguſt and ſeptember [15].

13. Stems ſeveral, erect, growing in tufts, about eighteen inches high, with harſh ſomewhat hairy angles, more or leſs reddiſh in the upper part, branched, leafy. Leaves moſt crowded towards the upper part, ſharply ſerrate, veiny, punctuated with ſhining dots, having a few ſhort hairs ſcattered over them, eſpecially about the margin, and along the nerves on the back. Their uſual ſcent is much like that of *M. viridis* or garden mackarel Mint; but nothing is more variable than the ſmell of Mints; (and we may add, than the judgment of different perſons on the ſame ſmell.) Mr. Sole has a variety of this, with the delightful ſcent of Baſil, to which Caſpar and John Bauhin's name alludes.—Bractes lanceolate, ciliate. Peduncles round, red, and always perfectly ſmooth, as is the lower part of the calyx; the upper part only, on or about the teeth, being fringed or clothed with hairs which point upwards. The pellucid globules on the calyx are very conſpicuous. Stamens ſhorter, ſtyle much longer than the corolla [16]; which is pale red, and has white hairs on the outſide and within the tube. Germs on a yelloviſh green fleſhy receptacle [17].

There is a Mint which agrees with this in the calyx and peduncle, but grows much taller, and has large ovate leaves. This many have taken for the true *M. gentilis*, but Dillenius ſeems to have confounded it with the *ſativa*, by his deſcription of the latter in Ray's ſynopſis.

Native of ſeveral parts of Europe in watery places and by the ſides of rivulets. Found by Mr. B. M. Forſter near Walthamſtow, and by Mr. Crowe and Dr. Smith on a ſmall common at Saham in Norfolk [18].

14. The whole plant is covered with ſoft white hairs, of a paler green than in *M. gentilis*. Stem not tinged with red, hairs pointing downwards. Leaves towards the top ovate-lanceolate; towards the bottom roundiſh. Whorls compoſed of two oppoſite ſeſſile umbels. Calyx pale green, beſet with ſoft white hairs, interſperſed with very minute ſemi-tranſparent glands. Corolla hairy within and without. Stamens in ſome plants longer than the corolla.

Native of many parts of Europe in watery places and moiſt corn fields.

It prevents the congulation of milk, and when cows have eaten it, as they will do largely at the end of ſummer, when paſtures are bare, their milk can hardly be made to yield cheeſe; a circumſtance which ſometimes puzzles the dairy-maids [19].

[9] Engliſh Botany. [10] Linn. [11] Withering. [12] Stokes in Withering. [13] Withering.

[14] Woodville. [15] Engliſh Botany. [16] Idem. [17] Withering. [18] Engl. bot. [19] Withering.

15. This resembles M. arvensis very much, but differs from it in being of a lower stature, in its smell, the shortness of the stamens, its greater hairiness, &c. Stems half a foot high and more, upright, almost simple. These, the leaves on both sides, and the calyxes are covered with a very short villous down. Leaves on short petioles, the lowest ovate, the rest lanceolate, acute, serrulate, the midrib hairy underneath. Flowers small, in very close whorls. Calycine toothlets equal. Corolla pale violet, with the upper lip emarginate or semibifid, and thrice as wide as the three segments of the lower lip: the throat is closed with white hairs. Filaments very short, concealed with the anthers in the lower part of the tube. It flowers in july and august.

Native of Austria, in the isles of the Danube [a]; and in Piedmont, according to Allione.

16. Linnæus compares this with his *exigua*, and says that the stem is higher, not branched, very hairy. Leaves narrower by half, sharper, more deeply serrate, of a darker colour, with hairs scattered over them and the calyxes; the teeth of which are almost equal. Corolla four-cleft; the upper segment oblong, longer, entire, the rest equal. Stamens within the tube. Style longer than the corolla.

Native of Canada, where it was found by Kalm [b].

Dr. Smith has discovered, after much investigation, that no such Mint exists as *M. exigua*, and that it is neither more nor less than *Clinia pulegioides*, a plant of North America [c].]

17. Pennyroyal has a fibrous perennial root. Stems smooth, and putting out roots at every joint. Leaves for the most part entire. Flowers towards the upper part of the branches, just above the leaves at each joint, in whorls. Corolla small, pale purple; upper lip entire. Stamens of the same length with the corolla, but the style somewhat longer. It varies with a white flower.

[Stems hairy, branched, with blunt corners. Leaves obovate, thick, slightly toothed, fer underneath with deep semi-transparent dots. Corolla twice as long as the calyx, hairy without. Filaments equal. Pistil as long as the stamens [d].

Native of many parts of Europe, on moist heaths and pastures: flowering in august and september.]

β. Stems erect, near a foot high. Leaves longer and narrower. Whorls of flowers much larger. Stamens longer than the corolla. This has almost superseded our wild one in the markets: the stems being more erect, it is easier to tie in bunches; it comes earlier to flower, and has a brighter appearance. It was sent to Mr. Miller from Gibraltar.

[Pennyroyal has a warm pungent flavour somewhat similar to Mint, but more acrid, and less agreeable. Its active principle is an essential oil, of a more volatile nature than that of Mint, coming over hastily with water at the beginning of the distillation, and rising also in great part with highly rectified spirit; in taste very pungent, and of a strong smell; when newly drawn of a yellowish colour with a cast of green, by age turning brownish.

Pennyroyal certainly possesses the general properties of Mint: it is supposed however to be of less efficacy as a stomachic, but more useful as a carminative and emmenagogue, and is more commonly employed in hysterical affections. We are told by Boyle and others, that it has been successfully used in the hooping-cough; but the chief purpose to which it has long been administered is promoting the uterine evacuation. With this intention Haller recommends an infusion of the herb with steel in white wine. However in the opinion of Dr. Cullen, Mint is in every respect more effectual than Pennyroyal, and nothing but the neglect of establishing principles could have made physicians regard this as a peculiar medicine distinct from the Mints; and accordingly this plant is less frequently used now than formerly. The officinal preparations are a simple water, a spirit, and an essential oil [e].]

18. Stems erect, near two feet high, sending out side branches all their length. Leaves very narrow, and of a thicker substance than those of common Pennyroyal. The whorls of flowers are rather larger, and the stalks are frequently terminated by them. The scent is not quite so strong as that of Pennyroyal. It flowers about the same time. There is a variety with white flowers, which grows taller than the common one with purple flowers. It is by some preferred to Pennyroyal for medicinal use. It is called Hart's Pennyroyal.

Native of the South of France and Italy. [Cultivated in the botanic garden at Oxford in 1648 [f].

19. This resembles *Perilla ocymoides*, and is the only instance of a Mint that is annual. The stamens are shorter than the corolla [g].

Native of the East Indies.]

Miller has some other species, as M. chalepensis, or Aleppo Mint, n. 10. with oblong, toothed leaves, tomentose on both sides and sessile, with very narrow spikes.—M. nigricans, or broad-leaved black Pepper Mint; a larger variety of his M. piperita (n. 6.) not of Linnæus: his M. piperita not being our true one.—M. rubra, or Orange Mint, n. 9. with oblong-ovate, acuminate, toothed, sessile leaves, and interrupted clustered spikes, probably a variety of the viridis or common Spearmint. There is also a Mint of his in the Banksian herbarium, which he names M. hispanica candidissima, fol. serratis, spicis florum longissimis, which seems to be a variety of M. sylvestris.

PROPAGATION AND CULTURE.

Mr. Miller has enumerated seventeen species, which (in the year 1759) he affirms that he had cultivated near thirty years, without observing any change in them.

All the sorts of Mint are easily propagated by parting the roots in the spring, or by planting cuttings during any of the summer months, but they should have a moist soil; and after the cuttings are planted, if the season should prove dry, they must be often watered until they have taken root; after which, they will require no farther care but to keep them clear from weeds: they should be planted in beds about four feet wide, allowing a path about two feet broad between the beds, to water, weed, and cut the plants.

The distance they should be set is four or five inches, or more, because they spread very much at their roots; for which reason, the beds should not stand longer than three years before you plant again, for by that time the roots will be matted so closely, as to rot and decay each other, if permitted to stand longer. Some persons are very fond of Mint salad in winter and spring; in order to obtain which, they take up the roots before christmas, and plant them upon a moderate hot-bed pretty close, covering them with fine earth about an inch thick, and cover the bed either with mats or frames of glass. In these beds the Mint will come up in a month's time, and be soon fit to cut for that purpose.

When the herb is cut for medicinal use, it should be done in a very dry season, just when it is in flower; for if it stand longer, it will not be so well tasted; and if it be cut when it is wet, it will change black and be little worth; this should be hung up to dry in a shady place, where it may remain until it be used.

If the soil be good in which these plants are set, they will afford three crops every year, but after july they seldom prove good; therefore what shoots are produced after that time should be permitted to remain till michaelmas, when they must be cut down close; and after having cleared the beds from weeds, you should spread a little fine rich earth all over them, which will greatly encourage the roots against the succeeding spring.

17, 18. Penny-royal and Hyssop-leaved Mint propagate very fast by their creeping stems, which may be cut off and planted in fresh beds, allowing them at least a foot distance every way. Or the young shoots planted in the spring, will take root like Mint.

The best time for this work is in september, that the plants may be rooted before winter. The young

[a] Jacquin. [b] Linn. spec. [c] Linn. transf. 3. 18. [d] Withering. [e] Woodville, Lewis. [f] Hort. kew. [g] Linn. syst.

plants also will be much stronger and produce a larger crop, than if they were removed in the spring. And if the roots remain so close as they generally grow, they are subject to rot in winter. They love a moist strong soil.

DESCRIPTION, &c.

This plant is annual; it rises with a slender smooth stalk, which is stiff, and becomes a little woody, rising more than three feet high, branching out alternately at distances; the branches are distorted, and run into one another; these are garnished with leaves shaped like the point of an halbert, standing alternately on the branches, upon short foot-stalks; they are covered with short hooded prickles, which fasten themselves into the clothes of those who rub against them; and those parts of the branches easily separate from the plants, and adhere to the clothes in like manner as the seeds of Clivers. The flowers come out singly from the joints of the stalk, resting upon a cylindrical germen, which is near an inch in length, narrow at the base, but widening upwards towards to the top. Upon the top of it comes out the calyx, which is spread open after the same manner as that of Onagra; then the petals of the flower spread open upon the calyx: they are of a pale yellow colour.

[Stems numerous, covered with short bowed bristles, three or four feet high, round, yellowish green, the lower branches alternate, axillary, the upper in pairs, forking again and again. Leaves alternate, ovate-lanceolate, doubly serrate, gashed at bottom, dark green above, whitish underneath, on short petioles; on the branchlets they are sessile. Flowers solitary, sessile in the forks of the branches. Calyx hispid. Corolla large, deep sulphur-coloured; petals inserted into the top of the calyx, somewhat fringed towards the tip, and ending in a dagger-point. Filaments yellow, inserted into the calyx in two rows, the ten or twelve outer ones longer, wider at the base, and bowing towards the centre of the flower, the rest upright: anthers ovate, upright. Germ inversely conical, very hispid, almost an inch long: style bristle-shaped, longer than the stamens. Capsule rough, inversely conical, succulent before it is ripe, but then dry, with three longitudinal grooves, and wrinkled. Seeds flatted-ovate, narrower at top, roughened with little prominent points.

Native of America—of La Vera Cruz, according to Miller—of Mexico, according to Cavanilles—of Curaçao, according to Jacquin—of Jamaica, according to Browne. He says it is very common in all the dry savannahs about Kingston: that it seems to be an annual plant, and seldom rises above three or four feet in height. He describes the fruit as a succulent cylindric capsule, well furnished with short rough uncinated bristles, like the rest of the plant, and containing only three or four rugged seeds, compressed on one side, and disposed at some distance from each other, in the pulp.

Jacquin describes it as an annual upright plant; and observes, as Cavanilles does, that the ripe capsule is not at all succulent. Plumier's plant, referred to this, seems to be a different species; the leaves being crenate, all the flowers axillary and not in the forks of the branches, the petals orbiculate and crenulate.]

Cultivated by Mr. Miller, from seeds sent over by Dr. Houstoun.

PROPAGATION AND CULTURE.

As this is an annual plant, which perishes soon after the seeds are ripe, therefore the seeds must be sown on a hot-bed early in the spring, that the plants may be brought forward early in the season, otherwise they will not produce ripe seed in this country. When the plants are come up about an inch high, they should be each transplanted into a separate halfpenny pot filled with light rich earth, and plunged into a hot-bed of tanners bark, being careful to shade them from the sun until they have taken new root; after which time they must be constantly watered every other day in warm weather, and should have fresh air every day admitted to them, in proportion to the warmth of the season, and the heat of the bed in which they are plunged. In about six weeks or two months after transplanting, if the plants have made a good progress, they will have filled the pots with their roots, when they should be shifted into larger pots, which must be filled with light rich earth, and then plunged into the tan-bed in the stove, that they may have room to grow in height, observing as before to water them duly, as also to admit fresh air to them every day in warm weather. With this management they will grow three feet high, and produce ripe seeds at the end of august or beginning of september.

MENYANTHES. [(*Menyanthes is reckoned by Theophrastus and Dioscorides, and* Minyanthes *by Pliny, among coronary trefoils.—Linnæus derives it from one a month, and anthos a flower: because the flower continues open about that time.*)

DESCRIPTIONS, *&c.*

Theſe are herbaceous aquatics. Leaves on a ſheathing petiole, ternate in the fourth ſpecies, in the reſt ſimply cordate. The flowers of the firſt are umbelled or in axillary whorls; in the fourth they are in a ſpike on a ſcape[a].

1. Root perennial, long and ſtringy, as are alſo the ſtems; theſe are ſmooth, round and jointed. They produce a few pairs of oppoſite, floating leaves, thick, repand-toothed, or rather waved than toothed, ſhining above, dotted beneath, on foot-ſtalks various in length according to the depth of the water. Theſe leaves, like thoſe of Nymphæa, to which this is allied in habit, perſpire ſo much as to become dry in a few hours, though at firſt very ſucculent. The flowers grow from the axils in a kind of ſeſſile umbel, four or five together, on long round peduncles, ſhorter than the petioles, and when expanded in the ſun have a brilliant appearance. Stipules ovate, without the peduncles but within the petioles. Calyx five-leaved; leaflets linear or lanceolate. Corolla twice as large as the calyx, yellow; ſegments inverſely ovate, the middle of each veined, and the part ſo veined bordered by two ſtronger veins, which, converging towards each end, give the appearance of a narrow lanceolate petal being laid upon it; they are finely toothed at the edge[b]. Capſule ovate-lanceolate, compreſſed a little, thickened and rounded at the edge, at firſt fleſhy then coriaceous, thin, one-celled, two-valved. Seeds numerous, bracted or leafy, ſurrounded by a white membranaceous ciliated margin, ovate or obovate, of a pale bay colour in the middle, fixed to the edges of the valves on each ſide in a double row[c]. The corolla being ciliated or only fringed about the edge, not all over the ſurface like *M. triſoliata*, Tournefort, Gmelin, Wiggers, Gærtner, and Dr. Stokes, would make it a ſeparate genus, nay Wiggers aſſerts, but without telling us why, that it even belongs to a different natural order. Monſ. de Juſſieu doubts whether they ought to be ſeparated or not, but as he has left them together, and *M. indica* ſeems to connect them, I readily agree with Dr. Smith that they may ſafely remain as they are[d].

Native of Denmark, Holland, Germany, Piedmont, Siberia, England; in large ditches and ſlow ſtreams. In the Thames, chiefly in little receſſes of the ſhores, as near Walton-bridge, near Botley-bridge, Godſtow-bridge, and Hinkley-ferry in Oxfordſhire. In the river Cam, Streatham-ferry, and in the fens near Ely, frequent. It flowers from june to auguſt.

2. Sloane deſcribes it as having a leaf like Colt's-foot, roundiſh and about two inches diameter, thick, yellowiſh green, ſmooth without any apparent nerves. Petioles about a foot long, more or leſs according to the depth of the water, on the ſurface of which they float; they are round and brownifh, and out of them come ſeveral white flowers, juſt under the leaf, on peduncles an inch long, or ſhorter.

Native of both Indies.

Rheede deſcribes the flowers as having ten ſtamens. Sir William Jones, in his ſelect Indian plants deſcribes another ſpecies, or perhaps variety, with the ſame number of ſtamens, five of which are ſterile. It is figured in t. 29. vol. 11. of Hortus Malabaricus. He calls it *Cumeda* or delight of the water, which ſeems to be a general name for beautiful aquatic flowers.

The leaves are cordate, peltate, bright green on one ſide, dark ruſſet on the other. Flowers umbel-faſciculed, placed on the ſtem juſt below the leaf. Glands and tube of the corolla yellow, border white, both of the moſt exquiſite texture. The diviſions of the corolla may be called three-winged: they look as if covered with ſilver froſt[e].

3. This has the appearance of Aliſma, with the flower of Menyanthes[f].

Found at the Cape of Good Hope by Thunberg and Maſſon, by the latter of whom it was introduced in 1786[g].

4. Root perennial, creeping, long, jointed and fibrous. Stem procumbent, various in length according to ſituation, covered by the ſheaths of the leaves, which are on round ſtriated petioles. Leaflets ovate, obtuſe, ſmooth on both ſides, veiny, with a waved or ſerpentine edge. Flowers on a ſimple, upright, round, ſmooth ſcape, longer than the leaves, in a naked and ſomewhat pyramidal terminating thyrſe. Bractes ovate, ſomewhat concave, pointed. Calyx wrinkled at bottom; the ſegments coloured on the edge. Corolla outwardly of a roſe colour, inwardly white; tube thick, longer than the calyx, five-grooved; ſegments of the border narrow and pointed, bearded on the inſide except at the tips: beard the length of the calyx, thready and white. Filaments faſtened to the tube of the corolla. Anthers purpliſh, ſagittate, with the tips curved inwards. Germ ovate, green, ſhining; ſtyle a little thickening above, twice the length of the ſtamens: ſtigma two-lipped, green, villoſe[h]. Capſule the ſize of a Pea, with a groove on each ſide contrary to the ſutures of the valves. Seeds many, but only ſix or eight ripening, very ſmooth, ſhining, lemon or ſtraw-coloured[i].

Formerly named Marſh Trefoil, and Marſh-Claver or Clover. Now generally called *Buck-bean*, I once thought corruptedly for Bog-bean, from its place of growth, and the form of the leaves. But one of its German names is *Bocksbone*, and in Daniſh it is *Bukkeblade*. Buck-bean (Faba hircina) therefore, whatever

[a] Jeſſieu.
[b] Engl. bot. Lyon's M. S. in Relh. cant. and Stokes in Withering.

[f] Linn. ſuppl. [g] Hort. kew. [h] Curtis. [i] Gærtner.

it means, is probably right. It flowers from may to july, and is found in wet boggy meadows, ditches, and the sides of ponds and lake. In Batterſea meadows, about the iſland of St. Helena near Rotherhithe, about Staines, on Bromley-common, between Farnborough and Caſton-mark, Caſar's-camp near Bromley, Hayes-common, Hampſtead-heath, Harefield-moor, ſeveral places in Cambridgeſhire, &c. but it is frequently rooted out by the ſimplers.

An infuſion of the leaves is extremely bitter, and of late years has been in common uſe as an alterative and aperient in impurities of the humours and ſome hydropic and rheumatic caſes. A dram in powder purges and vomits. It is ſometimes given to deſtroy worms. As an active and ecoprhoric bitter, it ſeems not ill adapted to ſupply the want of bile in the *prima viæ*; and thus may be of uſe in protracted jaundice and other biliary obſtructions. Cullen mentions ſeveral inſtances of its good effects in ſome cutaneous diſeaſes of the herpetic and ſeemingly cancerous kind. With delicate ſtomachs it may be neceſſary to join ſome grateful aromatic with the infuſion.

In a ſcarcity of hops this plant is uſed in the north of Europe to give a bitter to beer; two ounces will ſupply the place of a pound of hops. The powdered roots are ſometimes uſed in Lapland inſtead of bread, but they are unpalatable. Some ſay that ſheep will eat it, and that it cures them of the rot*.

5. This is a marſh plant like the reſt, with a filiform creeping ſtem. Leaves ſmooth, petioled, ſcattered, few. Flowers white, on long peduncles. Corolla hirſute, with a crenated border, and five branched nectaries of a different colour adhering to the baſe of the ſegments. This plant forms the connecting link between this genus and Hydrophyllum.

Native of Cochinchina[1].

PROPAGATION AND CULTURE.

Mr. Miller informs us that the common Buck-bean was never cultivated in gardens. It deſerves cultivation however, and both that and the firſt ſpecies may be kept in pots or tubs of water.

To ſuch as wiſh to have the Buck-bean flower in perfection, Mr. Curtis recommends to collect the roots in ſpring or autumn, to put them in a large pot having a hole in the bottom, and filled with bog-earth, and to immerſe the pot about two-thirds of its depth in water. The foreign ſpecies muſt be kept in pots or tubs of water in the ſtove.

Stem proſtrate herbaceous, leaves ovate ſubtomentoſe, flowers androgynous.
6. Mercurialis indica. *Indian Mercury.*
Lour. cochinch. 628.
Stem ſhrubby branched, leaves lanceolate even, flowers three-ſtyled.

DESCRIPTIONS, &c.

1. Root perennial, creeping, white, very fibrous. Stem upright, ſimple, a foot high, leafy, naked below, round, thickeſt at the joints, with two projecting ridges, not running down from the leaf-ſtalks, but from the joint between them, and terminating in the boſom of the pair below. Leaves in oppoſite pairs alternately from each ſide of the ſtem, ovate-lanceolate, wrinkled, ſerrate, pale green; the teeth blunniſh, and terminated by a whitiſh gland, viſible only with a magnifier. Petioles ſhort, furrowed, ſlightly hairy and rough to the touch. Peduncles axillary, near the top of the plant, oppoſite, hairy, in the male longer than the leaves,

in the female concealed among them. Flowers in the female few; in the male numerous, ſeſſile, growing in a ſort of whorl, and half ſurrounding the ſtem.

The male flowers have nine ſtamens for the moſt part: anthers firſt yellow, afterwards becoming blueiſh. The female flowers have the ſtyles rough on the inner ſide with ſemi-tranſparent tubercles. Dr. Withering aſks whether the nectaries are not rather rudiments of imperfect ſtamens. Capſule hairy, ſomewhat warty. Seed of a browniſh purple colour[a].

The male and female plants are rarely found intermixed, each ſort uſually growing in large patches; whence it is probable that this plant, which increaſes much by the root, rarely produces perfect ſeeds[b].

It is common in woods and under hedges, flowering from the end of march to the middle of may.

In the third edition of Ray's ſynopſis there is a very circumſtantial relation from Sir Hans Sloane, of a man with his wife and three children experiencing highly deleterious effects from eating this plant fried with bacon.]

Mr. Miller affirms that there have been many late inſtances of its poiſonous quality, from perſons in the ſpring, during a ſcarcity of greens, having boiled and eaten the leaves. [But he gives us no authority, and there are no inſtances on record except the ſingle one mentioned above. It would however be well to aſcertain the fact, becauſe it is a common plant, and the third ſpecies, which is not unlike it, is conſidered as a poiſon-herb, and is ſometimes uſed as an emollient.

Linnæus ſays, that M. perennis is noxious to ſheep. With us, no quadruped ſeems to eat it.

In drying, it turns blue, and ſteeped in water, it affords a fine deep blue colour, but which, ſays Dr. Stokes, is unhappily deſtructible both by acids and alkalies, and recoverable by no means that he has been able to diſcover.

2. Root fibrous, annual. Stem a ſpan high, upright, four-cornered, very ſmooth, very ſimply branched near the root. Branches very few, oppoſite, ſhort, ſpreading. Leaves oppoſite, horizontal, cordate-ovate, equally ſerrate; ſerratures fewer, remote: they are bluniſh, ciliate, ſmooth on both ſides, veined, flat. Branch-leaves lanceolate, on ſhorter petioles. Petioles channelled, almoſt erect, very ſmooth, one-third of the length of the leaves. Stipules in pairs, lateral, deciduous, lanceolate, erect, very ſmall. Glands four, at the baſe of the leaves, two on each ſide, one larger than the other, pear-ſhaped, ſmooth, very ſmall. Flowers axillary, ſeveral, cluſtered, each on its proper pedicel: female ſingle, opening firſt; males ſeveral (three or four), lateral, in the ſame axil with the female. Calyx of the male pale, ſegments acute, entire, ſmooth, ſcarcely concave. Filaments nine or eleven. In the female flower the calyx is ſmaller. Style none. Stigmas two, reflex, hiſpid. Capſule compreſſed, truncated at top, very ſmooth at the ſides and grooved, the angles hiſpid.

It reſembles the next ſpecies very much, but all the flowers are pedunculed, each on its peculiar pedicel, and not diſpoſed in a raceme. The whole plant is more ſhining; the leaves broader, with the ſerratures more acute and ciliated; the capſules more hiſpid, not rounded but truncated at the top.

Native of Spain, on the walls of Cadiz and Gibraltar[c].

3. Root annual, fibrous, white. Stem a foot or eighteen inches high, upright, ſmooth, frequently tinged with purple, branched quite to the bottom, ſwelled at the joints, ſomewhat flattened; a prominent line runs on each ſide of the ſtem, from one joint to another, alternately. Branches alternately oppoſite, leafy, reſembling the ſtem. Leaves oppoſite, ovate, bluniſh, ſpreading, having two glands at the baſe, bluntly and diſtantly ſerrate, when magnified appearing edged with hairs, light green, ſomewhat gloſſy and veined: they are ſometimes ovate-lanceolate, lanceolate, and even cordate. Petioles much ſhorter than the leaves, ſmooth, channelled above. Stipules four at each joint; two on each ſide, very minute. Pedunculs axillary, oppoſite, upright, naked; in the male longer than the leaves, obſcurely four-cornered, producing towards the top ſeveral round, ſeſſile, ſmall cluſters of flowers, having a ſtrong viroſe ſmell, ſomewhat like that of Elder: in the female the pedunculs is ſhorter than the leaves and generally ſuſtains two flowers: the calyx in both flowers is permanent; in the female the leafets are a little ſmaller. Nectaries two, one on each ſide of the germ. According to Lightfoot theſe nectaries, or barren filaments, as he calls them, are wanting. Stigmas on the upper ſide hiſpid lengthwiſe[d]. Capſule dicoccous, ſmall, the upper parts ovate, turgid, hiſpid with white briſtles on the back, which near the future unite in two very narrow creſts; towards the axis they are ſmooth, ſub-compreſſed, papery, two-valved, opening elaſtically. Seeds one in each part, globular, rough with tubercles, rufeſcent or aſh-coloured, terminated at top by a fungoſe, fiſtular, whitiſh umbilicus[e].

This may be diſtinguiſhed from perennial or Dog's Mercury, by its annual root, its branched ſtem, its more numerous flowers, its want of nectaries or barren ſtamens, and its ſmaller hairy ſeed-veſſels. It alſo flowers late in the ſummer, whereas Dog's Mercury flowers only in the ſpring.

Native of many parts of Europe, with us in waſte places and dunghills about towns and villages,] ſeldom, as Miller obſerves found at a diſtance from habitations, hence he conjectures that it might originally have come from France, as its common name of French Mercury implies. [It is only mentioned by Gerarde to grow under the dropping of the biſhop's houſe at Rocheſter, and by Parkinſon in Romney-marſh. It ſeems to be much more common now than formerly, which countenances its not having been originally indigenous.

This plant is mucilaginous, and was formerly much employed as an emollient. Tournefort informs us, that the French made a ſyrup of it, two ounces of which was given as a purge; and that they uſed it in clyſters and peſſaries, mixing one part of honey with one and a half of juice. In England it is now diſregarded. The ſeeds taſte like thoſe of Hemp[f].

Two hybrid varieties of this ſpecies, one with linear or capillary leaves, and another with laciniated leaves, are deſcribed and figured by Marchant in the Paris Memoirs for 1719.]

4. This riſes with a ſhrubby branching ſtem a foot and half high. Leaves oppoſite, elliptic, ſharpiſh, involuted, covered with a white down on both ſides. The male flowers grow in ſhort ſpikes from the ſide of the ſtem and branches. Capſules hoary.

Native of the South of France, Spain and Italy. [Cultivated by Mr. Miller in 1731[g].

5. Stem branched, diffuſed, pubeſcent, often creeping. Leaves heaped at the joints of the ſtem, blunt, three-nerved, petioled. Pedunculs axillary, lateral, briſtle-ſhaped, one-flowered, the length of the leaves. Male flowers many; females fewer on the ſame plant. Fruit ovate, truncated, compreſſed, grooved with two ſtyles, fiſſile into two ſeeds.—Found at the Cape of Good Hope by Koenig[h].

6. Stem upright, ſix feet high, with round, aſcending branches. Leaves ſerrate, ſhining, alternate. Number of ſtamens inconſtant, frequently about fifteen, and ſometimes almoſt fifty. Capſule three-lobed, three-celled.—Native of Cochinchina.

The freſh leaves boiled in ſoup purge gently[i].

PROPAGATION AND CULTURE.

The firſt ſpecies is eaſily propagated by the roots: the third by the ſeed, which it ſcatters ſo abundantly in gardens as to be a common weed.] If the ſeeds of the fourth be permitted to ſcatter, they will come up the following ſpring; and if ſown, it ſhould be in the autumn.

This plant ſhould have a warm ſituation, and a dry rubbiſhy ſoil, in which it will live three or four years, but in hard froſts it is frequently killed.

Class. 12. 4. Icosandria Pentagynia.

Nat. order of *Succulentæ*. *Ficoideæ*, Juss.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-cleft, superior, acute, spreading, permanent.

COR. one-petalled: *petals* lanceolate-linear, very numerous, in several rows, a little longer than the calyx, slightly united at the claws into one.

STAM. *Filaments* numerous, capillary, the length of the calyx. *Antheræ* incumbent.

PIST. *Germ* inferior, with five blunt angles. *Styles* commonly five, awl-shaped, upright and then bent back. *Stigmas* simple.

PER. *Capsule* fleshy, roundish, the navel marked with rays, the cells corresponding with the styles in number.

SEEDS very many, roundish.

OBS. M. geniculiflorum, noctiflorum, tortuosum *are four-styled.*

M. linguiforme, pomeridianum, pugioniforme, barbatum, acinaciforme, loreum *are ten-styled.*

ESSENTIAL CHARACTER.

Cal. five-cleft. *Pet.* numerous, linear. *Caps.* fleshy, inferior, many-seeded.

Leaves alternate cluſtered axil-ſhaped three-ſided very long undotted.

**** *With green corollas.*

[74. Mesembryanthemum viridiflorum. *Green-flowered Fig Marigold.*
Ait. hort. kew. 2. 196. *Curt. magaz. t.* 326. *Haworth monogr.* 199.
Leaves ſemicylindric papuloſe-hairy, calyxes five-cleft hirſute.

---

75. Mesembryanthemum capillare.
Lin. ſyſt. 470. *ſuppl.* 260.
Leaves connate round papuloſe, ſtem upright, branchlets one-flowered filiform ſmooth.

DESCRIPTIONS, *&c.*

Of this very numerous and ſplendid genus very few are annual, fewer biennial, many are perennial, but moſt are ſhrubby, eſpecially towards the baſe. Leaves moſtly oppoſite, ſeldom alternate, thick or ſucculent, of various forms. Flowers ſolitary, axillary or extra-axillary, but more frequently terminating. The fruit is ſometimes ſhaped like a fig[a].

The annual ſorts are, nodiflorum, cryſtallinum, copticum, apetalum, limpidum, pinnatifidum, ſeſſiliflorum, glabrum, Helianthoides, pomeridianum. The biennials, caducum, Tripolium, papuloſum.

Linneus has ranged the ſpecies from the colour of the flowers, which is obvious, and ſufficiently conſtant, with few exceptions. Mr. Haworth has changed the order, and arranged the perennial ſorts chiefly from the leaves, thus—1. Subaphylia or almoſt leafleſs. 2. Subacaulia foliofa, almoſt ſtemleſs and leafy. 3. Cauleſcent with flat leaves. 4. Suffruteſcent with the leaves rounded underneath. 5. Suffruteſcent with three-ſided leaves.

They are chiefly natives of the Cape of Good Hope. Three or four of the ſpecies keep their flowers cloſed all day, and open in the evening; hence ſome have called theſe *Nyctheranthemum*, but as they agree with the reſt in other circumſtances, particularly in the fructification and habit, the diſtinction is abſurd.]

1. This is a native of Egypt, where they cut up the plants and burn them for pot-aſh; it is eſteemed the beſt ſort for making hard ſoap and the finer glaſs. It is an annual plant. In the ſtove the ſtalks grow long and ſlender, and are not productive of flowers. Raiſed in a hot-bed, and afterwards expoſed to the open air, it flowers freely. [It alſo grows wild in Italy, about Naples, on high ſea banks expoſed to the ſpray.

Stems decumbent and diffuſed, the whole plant papuloſe. Calyxes thick, five-toothed, two of the teeth larger, leaf-ſhaped. Petals very narrow, but flat, connate at the baſe. Stigmas generally five, ſeldom four[b].

It was cultivated in 1748, by Mr. Miller, and flowers in auguſt[c].

2. This is a charming little ſhrub, with a perennial fibrous root, and ſlender, but firm, nearly upright, ſtraight branches, which are thickly adorned with green, dotted, very ſmall, ſhort, triquetrous leaves. The ciliæ are not always obſervable[d].—Found at the Cape by Maſſon. Introduced in 1774[e].

3. This is another ſpecies found at the Cape by Maſſon. It was introduced in 1774, flowers in july and auguſt, and is biennial[f]. We have not any deſcription of it.]

4. This is an annual plant, diſtinguiſhed by its leaves and ſtalks being cloſely covered with pellucid pimples full of moiſture, which, when the ſun ſhines on them, reflect the light, and appear like ſmall bubbles of ice, whence it is called the *Ice-plant*; others name it the *Diamond Plant* or *Diamond Flower*.

[The ſtem has oppoſite and alternate cylindrical branches, which when luxuriant trail upon the ground, and are from one to two feet long. The firſt four or

[a] Jaſſieu. [b] Forſk. [c] Hort. kew. [d] Haworth. [e] Hort. kew. [f] Idem.

ſix leaves are oppoſite, each pair croſſing the other, very lax and ſucculent, waved, blunt, attenuated or wedge-ſhaped at the baſe, and connate, rather keeled underneath, eſpecially at the baſe, with a ſlight correſponding channel along the centre of the upper ſurface, which is covered with leſs and duller pimples than any other part of the plant: margin regularly edged, with globular papulæ or pimples, which are leſs than thoſe on the ſtems: the upper leaves are alternate, growing leſs and leſs, nearly ſeſſile, ſmall. Peduncles extremely ſhort or none, alternate, from the axils of the upper leaves. Segments of the calyx unequal, three of them large and leafy, beſet with pellucent pimples, and acutely pointed, the two inner much ſmaller, frequently coloured with a purpliſh tinge, acute at the points. Petals very narrow, bluſh-coloured without, whiteiſh within, ſometimes entirely white, making a poor appearance. Germ ſmooth, with a navel at the top. Styles five, longiſh, not ſtraight[a]. Capſule inferior, or united with the belly of the calyx beyond the middle, ſmooth, obſcurely five-cornered, five-celled, frequently purpliſh, opening at top by five cleſts which are thickened about the margin: cells narrow clothed with a cartilaginous lamina: partitions ſpongy, thick, narrowing like a wedge towards the axis. Seeds as many as twenty-five in a cell, ſmall, flatted a little, kidney-form triangular, ſomewhat wrinkled[b].

Native of Greece, near Athens, where it was found by the late John Sibthorp, M. D. Profeſſor of Botany at Oxford. It was cultivated here in 1727, as appears from Bradley. It flowers in july and auguſt[c].

5. This is a native of the Cape, where it was found by Maſſon. Introduced here in 1774. It flowers in july and auguſt. It is one of the ſhrubby ſorts[d], but we have no deſcription of it.

6. This is of the ſame ſtature and ſize with M. nodiflorum. Stem trichotomous, herbaceous. Leaves oppoſite, terminating the branchlets, the length of the internodes. Flowers ſeſſile, ſolitary, in the forks of the branches. Calyx longer than the corolla. Capſule turbinate, retuſe, five-angled, the angles ciliate, compreſſed. Seeds roundiſh, ſomewhat ſcrew-ſhaped, ſtriated. This is an annual, and a native of Egypt.

7. This is alſo an annual. Stems herbaceous, round, red. Theſe and the whole plant are covered with obſolete, papuloſe, ſhining dots. Leaves oppoſite, channelled above, ſemicylindric underneath, ſomewhat muricated, blunt. Peduncles ſhort, one-flowered. Leaflets of the calyx unequal, ſubulate-cylindric. Petals twenty-four, white, diſtant, briſtle-ſhaped, very ſhort, reſembling filaments without anthers, incumbent on the germ. Filaments very like the petals, but ſhorter. Anthers browniſh. Germ orbiculate, large, convex, ſmooth and even above. Styles five, approximating, ſhort. Stigmas recurved[e].

M. copticum of Jacquin is ſuppoſed to be this ſpecies and not the *copticum* of Linnæus. He obſerves, that the ſtems are very ſhort, diviided into branches that appear to be ſtems; that the flowers are about fourteen only; the filaments of the ſame length with the petals, with red anthers; the ſtyles thick, hirſute and reflected. In other reſpects his deſcription agrees with that given above from the ſupplement of the younger Linnæus.

Native of the Cape. Introduced in 1774, by Mr. Francis Maſſon. It flowers in july and auguſt[a].

8. Plant, whilſt young, herbaceous, but becoming ſhrubby by age. Trunk then woody, a finger or more in thickneſs, covered with a browniſh aſh-coloured bark. Branches decumbent, divaricating whilſt young, cylindric, tender, covered with minute pimples, dark green, thick, fleſhy, the bark, when old, becoming ſomewhat woody, and aſſuming various flexuoſe contorted directions: all the branches are nearly of the ſame thickneſs, but the upper ones are ſhorter, and more woody next the ſtem. Leaves moſtly oppoſite, but not always ſo, eſpecially on the flowering branches, ſmooth, cylindric, convex beneath, ſlightly channelled above, minutely pimpled. Flowers ſmall, making a poor appearance. Peduncles very ſhort and thick, ſolitary, remote, one-flowered, uſually axillary, but ſometimes terminating. Calyx ſtudded with larger papillæ than any other part of the plant; quadrifid, ſegments unequal; two large, leafy, channelled above, two leſs, ſubcylindric with the edges ſomewhat membranaceous. Petals dull yelloweſh white or pale ſtraw-colour, linear, entire or emarginate, reflex, the inner ones gradually ſmaller. Anthers ſub-didymous, large for the ſize of the flower; pollen yellow. Styles four, ſhort. Capſule fleſhy, finally ſemitranſparent, quadrangular, four-celled. Seeds few, neſtling in the pulp[b].

Native of the Cape. Cultivated in 1727, according to Bradley. It flowers from june to auguſt[c].

9. The trunk, which attains the thickneſs of the little finger, is ſmooth and even, covered with a bay-coloured bark, and has frequent joints where branches have fallen. Branches oppoſite, ſpreading irregularly, and decumbent from the weight of the leaves. Leaves pale green and ſlightly glaucous, obtuſely triangular, ſmooth and even, opaque, minutely and thickly dotted ſo as to make a very fine net: the lower ones longer; the upper ones, whence the peduncles ariſe, ſhorter and thicker. Calyx four-cleft. Petals narrow, the inner ones gradually ſhorter, inwardly white, outwardly purple. The flowers are cloſed during the day, open in the evening and continue open during the night, at which time they are very ſweet. Styles four. Capſule four-celled. Two ſegments of the calyx become ſmaller and almoſt membranaceous as the flower opens, and diſappear as the fruit ripens.

β. This differs no otherwiſe from the purple one than in the flowers being ſomewhat larger, and of a different colour, namely of a very pale yellow on the outſide[d].

Native of the Cape. Cultivated in 1714, by the Dutcheſs of Beaufort. It flowers from june to auguſt[e].

10. Stems woody, a foot and more in length, with many ſhort branches and cluſtered leaves, with which they are ſo loaded that they cannot ſupport themſelves. Leaves ſhort, bluntly three-ſided, thick, ſmooth and ſhining, pale green ſcarcely if at all glaucous, with a few thick green dots. Flowers ſolitary at the ends of the branchlets, on very ſhort peduncles, large, whiteiſh or very pale yellow within, reddiſh on the outſide and at the tips. Petals very narrow, the inner ones gradually ſmaller. They appear in july and auguſt, and open before and after noon, when the ſun ſhines, opening and cloſing ſeveral times, and finally cloſing about the fruit, which is ovate, with five lines or angles, five-celled. The five ſegments of the calyx are nearly equal[f].

According to Mr. Haworth, the ſegments of the calyx are blunt, large and long, three with large membranaceous edges, two nearly cylindrical, rather longer, without membranes, very blunt, and reſembling the leaves of the plant. The flowers whiteiſh, not ſhewy or large.

Native of the Cape. Cultivated in 1710, as appears from Bradley[a].

11. Stems woody, forming a regularly branched handſome ſhrub, ſtanding without ſupport with a ſtout ſtem, from two to three feet high and even more. Branches many, ſpreading every way, having four lines running along them, which give them the appearance of being quadrangular. Leaves ſubtriquetrous, wrinkled, bending this way and that, ſomewhat reſembling bull's horns, glaucous except the younger ones, which are green and leſs wrinkled, when held up to the light they appear to have innumerable pores. From one axil of each pair of leaves, ſometimes from both, one pair of leaves uſually ſpringe, which becomes a ſhoot, with ſeveral pairs of leaves on it. Flowers terminating, white, opening when the ſun ſhines from ſeven or eight in the morning to two or three in the afternoon, and ſmelling like thoſe of May or White-thorn. Capſules ſmall, roundiſh, ſomewhat angular with five

blunt ribs and five-celled. Seeds ſmall, ſubrufous[1]. Native of the Cape. Cultivated in 1727, as appears from Bradley. It flowers from june to ſeptember[2].

12. Stems and branches irregular and diſtorted, as in *tortuoſum*, from which however it differs in being ſomewhat higher and more branched; the branches interwoven, leſs woody, but ſofter and more fleſhy, with the bark ſmoother and of a paler yellow; the leaves greener, ſomething wider and thinner, with the ridge on the outer and the groove on the inner part more conſpicuous, though leſs concave; the dots rather oblong than round, ſhining like ſilver in the ſunſhine; they are not produced in bundles, as in *tortuoſum*, but more looſely, and decuſſated. Flowers ſomewhat larger and paler; the petals rather wider, and becoming yelloſwiſh with age. Calyx and capſules larger and more ſwelling.

The inner petals are yelloſwiſh, the outer larger and whitiſh with a very ſlight tinge of yellow, ſhining in the ſun. Three of the calycine ſegments are larger and two ſhorter; ſometimes three ſmaller and two larger. Capſule globular, with five grooves, and as many rays at the top, five-celled[3].

Native of the Cape. Cultivated in 1705, by Dr Uvedale. It flowers in july and auguſt[4].

13. Stemleſs, very white and ſhort. Rarely more than four living leaves on a plant at once, and of theſe the oldeſt pair often leſs plump than the other. All the leaves are connate below, extremely ſhort and thick, but much thicker at the baſe than towards their blunt points, rounded on the outſide, flat within[5].

Native of the Cape, where it was found by Maſſon. Introduced in 1774[6].

14. Plant the ſize of the common Daiſy. Leaves ovate-oblong, petioled, with cryſtalline dots. Scape an inch long, one-flowered. Calyx deeply five-cleft; ſegments oblong, very blunt. Petals five, oblong, pedicelled, longer than the calyx, white. Stamens briſtle-ſhaped, white, very long.—Found at the Cape of Good Hope by Montin[7].
